Blame for such substitution of cheap contacts cannot rest entirely upon the manufacturer so long as the users of electric signalling apparatus fail to recognise the value of the higher-priced article, or, recognising it, fail to specify its use when awarding contracts, and to see that this vitally important detail has been honestly and intelligently executed in the completed instruments.

In municipal work, more than in any other, the electrical equipment must be absolutely reliable. A bad contact, sticking together or full of oxides, may mean loss and danger of the gravest sort to the community. Through failure of the fire apparatus to respond to an alarm, or of the ambulance to answer its call, or of the police to appear promptly when summoned, a bad contact may exact a fearful toll in conflagration, or death, or riot; and in the saving of a few cents' worth of platinum the vast expenditures of municipalities for fire and police protection, and of the generous public for hospitals, may be *nullified*. There is no room for economy of this wasteful kind in instruments upon which so much depends, and to which, owing to the careful and conscientious superintendence of the members of this association, the public looks with perfect confidence for perfect results.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of the Institution held on Thursday, Nov. 22, Mr. John Gavey read his paper on "Telegraphs and Telephones at the Paris Exhibition," an abstract of which appeared in our last issue. In the discussion,

Sir W. H. Preece said it did his heart good to see such a large audience to hear an address which had telegraphs and telephones for its text. It reminded him of the early days of telegraphy, when sensation after sensation was described, and ringing applause from such full audiences was heard. He wondered if the younger members of the Institution ever read of the early days of telegraphy; they would learn a great deal by so doing. This was not the first time that a paper had been read at the Institution dealing with the exhibits at an exhibition. He himself had brought before it papers dealing with exhibits at the Paris, Chicago, and Philadelphian Exhibitions. He hoped the practice would continue, and that by hearing of the improvements and inventions carried out in other parts of the world they would not let the profession in this country fall behind the practice in others. It was a remarkable fact that the growth of a business was in proportion to its capacity for carrying out that progress. Mr. Gavey had shown them some great improvements in telegraphs, but this axiom or maxim was not confined to telegraphy. It was true of the telephone, of electric traction, and of every branch and application of electricity to the industries. It was never more strongly shown in England and America than by the fact that as the length of telegraph wire increased, there also increased in arithmetical ratio the carrying capacity of the line, and at the present time a circuit would carry 10 times as much as it carried when first the Institution made use of that room. It was some 23 years since the telephone was first shown at Plymouth, and it was still questionable if telephony in England was flourishing. They saw a sort of triangular duel going on. They saw a company which was striving hard to give a good service to the public, and they saw municipalities trying to emulate their competitor. There was another small department, called the Post Office, which was also trying to do its duty, and it had the advantage over the other competitors that its back was broad enough to bear all the abuse put upon it. He thought that such a business as telephony should be manipulated by one concern only, and that it should be conducted upon one principle

Digitized by Google

only. He had once hoped to see a telephone in almost every house, but he was afraid he would never see his hopes realised. As to wireless telegraphy, they were getting tired of it. The papers still took it up wildly, but there did not seem to be any progress made with it. If there was a single circuit now working practically, he hoped that someone would read a paper to them on it. The most beautiful thing which Mr. Gavey had brought to their notice was the microphonograph. He thought it was a thing which was coming to stay, and it was marvellous. It was not only based on beautiful principles, but it was one of those things which was going to open the eyes of physicists as to the character of molecular magnetic operations. There was nothing to his mind so wonderful as the molecular magnetic action in steel. As to the altering of the names of the constants, Mr. Gavey had not mentioned the names given. Thus the name given to the unit of magnetic field was the "gauss," and to the unit of magnetic flux the "maxwell." He did not think the "maxwell" would come into general use, although it might be shortened to "max." He thought, however, that the name "gauss" would be taken up for the unit of magnetic field.

Mr. W. J. Hammer, of America, said that while on the Continent he had seen one thing spoken of by Mr. Gavey, and this was the "telephonograph." He had recently been in touch with some of the people connected with the invention, and they expressed a strong desire that the name "telephonograph" should be used. In Berlin he had also seen some modifications of it and some interesting experiments, but he could not say anything further concerning them, as he had seen these experiments in a peculiar way. He had had considerable experience in working with phonographs and their modifications, but had never heard anything in the way of a speaking machine which was so clear as the telephonograph. There was no scratching sound as with an instrument where the record was made with a style. He had the pleasure of seeing the Nernst lamp in operation in Paris, but the subject was one which hardly came under the heading of the paper. In Budapest he had seen the Pollak and Virag system of telegraphing, and in the present form it was a most beautiful thing, and seemed to work satisfactorily.

Mr. M. F. Roberts said that the author had mentioned the difficulty he had in explaining certain apparatus by the request made that he would not publish diagrams of it. This was one of the difficulties he himself had experienced in the Paris Exhibition. The exhibits in most instances were placed in the charge of attendants who either did not understand them or who had been told to give no explanation of them. The catalogue was also a great difficulty, many people being unable to obtain information owing to its bad preparation. He thought that the improvements spoken of, with one or two exceptions, were points of detail. He would have been glad if Mr. Gavey had extended his remarks with reference to the improvements since the 1878 exhibition. He thought the improvements in the telegraph were mainly in the higher finish of the instruments, and in the telephone they were chiefly the simplification of the design of the parts. The standardisation which appeared in the telephone parts was mainly, he thought, due to the influence of one or two firms and to the employment by these firms of men who made a study of certain apparatus—such as switchboards, dynamos, telephone instruments, etc. By this means men were obtained who brought the special part to its highest efficiency. The author had also called attention to Rowlands's apparatus. From the earliest exhibitions there had always been some such machines, but they had not made much headway. He hoped the successful exhibits of the Rowlands Company would have the effect of popularising the typewriting telegraph in this country.

A communication was then read from **Mr. A. W. Heaviside**, president of the Newcastle Section, thanking Mr. Gavey for his paper, and asking questions on certain of the points raised.

Mr. Dane Sinclair said the improvements in telegraphy which were described were very beautiful. He thought it possible that Mr. Gavey might be too enthusiastic over the central battery system. As to the microphonograph, or telephonograph, as another gentlemen called it, he would say, in justice to Mr. Gavey, that it was called a microphonograph at the Exhibition. For once in his life he had been ahead of his good friend Sir W. H. Preece, and had seen the apparatus at work. It gave a distinct record of speech, so distinct that it could not be compared with any record he had hitherto heard. The sounds came back pure without the grating sounds usual in the ordinary phonograph. The Post Office, under Sir W. H. Preece, had erected heavy copper wires all over the country, but if only a telegraphic relay could be obtained these would soon get out of date.

Mr. J. E. Kingsbury, in referring to the Bell system, said that while they gave every credit to the professor for his invention, it was yet rather early to remark upon it. He would like to say one word as to the application made by the Post Office of automatic signalling. The Post Office had installed this automatic system, and, much to the surprise of some people, had stuck to it. The central battery system was not a system of to day, for 20 years ago a patent had been taken out for it. Mr. Sinclair had thought Mr. Gavey too sanguine. He should like Mr. Sinclair to give his reasons for thinking so. With regard to the telephonic repeater, he would remind Mr. Gavey that the question was of an earlier date than 12 years ago, as Mr. Gillman took out the first patent for a repeater in 1879. The first repeater seemed to have been a more practical working instrument than the present one.

Dr. S. P. Thompson said there were three points of interest. The new magnetic units with which the Paris Congress had endowed them were certainly a great boon in speaking of magnetic quantities. They were able to say definitely that a magnetic field had an intensity of ·18 gauss, instead of saying ·18 alone, which seemed to hang on nothing. He was not sure that the "maxwell" would be such a success. They already had a good word for the field of the magnetic flux in the magnetic line, and the word "line" was easier to use. He had had the pleasure of inspecting the Slaby-D'Arco system in Berlin, and to witness its working from Berlin to Oberweide. He did not think that the diagram shown, which looked like two sausages hung up, gave one a good idea of the apparatus. Each of those sausages was a wire cage consisting of six or eight wires about 150ft. long, and hung up from a tall chimney perhaps. It was a remarkable thing that one could get messages recorded on the apparatus when both terminals were earthed. He would like to bear testimony to the extraordinary goodness of the recording phonograph and telephone which he saw in Paris. When he saw the instrument in Paris it was called the telegraphon.

Mr. J. Gavey, in reply, said Mr. Roberts referred to the desirability of giving more detail of the improvements in telegraphs and telephones which had taken place since 1878. In composing this paper he had rather tried to make it suggestive than to state definitely what the improvements were. It would take a treatise on telegraphy and telephony to do this in detail. Much apparatus which was prominent in the Paris Exhibition of 1878 had not found a place this year, and *vice versâ*. One improvement he thought was wanted. Their good friend and servant the Morse system had served them long and well, but he thought it hardly up to the present requirements. He was rather looking forward to something of the Rowlands type, by which the messages could be received in a condition to be sent out, and without the necessity of transcribing. He had no wish to depreciate Prof Hughes's beautiful instrument, but he thought they would admit that it was preferable to have the message ready printed or typed. Mr. Roberts's remarks were true in that the improvements had been in matters of detail, but the speaking instrument must consist of a transmitter, line, and receiver, and when these were had, improvements could only be in matters of detail. He ventured to think that the improvements in detail during the last four or five years had amounted almost to a revolution. Prof. Thompson had referred to the sausage-like appearance of the cages in his Slaby and D'Arco diagram, but these were almost exact reproductions of those on the pamphlet supplied by the inventors at the Paris Exhibition.

Prof. Perry then asked for the usual vote of thanks, which was unanimously accorded.

Several pieces of apparatus were shown on the table.

The following is a list of the candidates balloted for:

Members.—J. Franklin, telegraph superintendent, B.B. and C.I. Railway, Bombay, India; R. Robertson, B.Sc. (Edin.), M.I.C.E., 154, West George-street, Glasgow, N.B.; W. H. Trentham, 39, Victoria-street, S.W.

Associate Members.—L. J. Aron, Aron Electricity Meter, Limited, 46, Upper Thames-street, E.C.; M. H. Bennett, 71, Queen Victoria-street, E.C.; R. Beveridge, Messrs. Powlesland, Beveridge, and Co., Plymouth; J. Bowden, Sheriff-mount, Gateshead-on-Tyne; G. D. Dauncey, Suffolk-road, Sheffield; J. Lambert, Electric Light Station, Dundee, N.B.; J. T. Morrison, Victoria College, Stellenbosch, Cape Colony, S.A.; W. E. Pennefather, Electric Power Station, Second Basin, South Esk River, Launceston, Tasmania; H. N. Thomas, 42, Luck-lane-marsh, Huddersfield.

Foreign Members.—Prof. R. Arnó, Instituto Tecnico Superiore, Milan; Prof. M. de Châtelain, Wasili Ostrow 10 Line, No. 5, St. Petersburg, Russia; G. Semenza, Società Edison, Milan; W. G. Thomsen, Jydsk Telefon, Aktieselskab, Aarhus, Jutland, Denmark.

Associates.—W. J. Baker, 327, Blackburn-road, Bolton; G. E. Cummins, 4, Williams-terrace, High-road, Chiswick, W.; A. J. Drakes, Chief Engineer's Office, G.P.O., Capetown, S.A.; E. G. Fenning, 3, St. Matthew's-road, St. Leonards-on-Sea; W. Gaye, Eastern and South African Telegraph Company, Capetown, S.A.; J. O. G. Gibbons, 451, Shelford road, Old Trafford, Manchester; G. Gordon, 4, Haddon-terrace, Mowbray, Capetown, S.A.; I. B. Hadaway, Metropolitan District, G.P.O., Capetown, S.A.; E. P. Harvey, Purland Chase, Ross, Herefordshire; A. Henry, 8, Kimberley-terrace, Observatory-road, Capetown, S.A.; C. F. M. Hibberd, 44, Dewhurst-road, Shepherd's Bush, W.; F. Holland, 178, Ashton New-road, Manchester; R. H. Kent, 54, Darley-road, Stamford Hill, N.; G. K. Nowlan, Sirdar House, 79, Valley-drive, Harrogate, Yorks; D. Page, 33, Bedford-street, Strand, W.C.; W. H. Ridpath, 41, Princess road, Kilburn, N.W.; F. H. Rippon, 7 and 8, Queen-street, Exeter; E. L. Rossiter, Elsteinwick, Victoria; A. R. Turner, c/o Messrs. W. Denny and Bros., Dumbarton, N.B.; H. Wragg, 176, London-road, Sheffield.

Students.—E. R. Alexander, 35, Birdhurst-road, Croydon; D. R. H. Browne, King's College, London, W.C.; O. H. Browne, the Court House, Kingsthorpe, Northampton; H. L. Churton, Hillside, Chester; R. C. Creasey, Star and Garter Royal Hotel, Wolverhampton; E. De Lautour, 34, Aldridge-road-villas, Westbourne Park, W.; C. H. Fisher, Highfield, Hamlet Court-road, Westcliff-on-Sea, Essex; R. B. Forster, Wynnstay, Roebuck, Milltown, co. Dublin; R. W. Gregory, 26, Great Peter-street, Westminster, S.W.; S. H. Harris, 2, Capel-road, Faversham, Kent; A. L. Kavanagh, Mercers' Hall, Ironmonger-lane, Cheapside, E.C.; R. M. Longman, 26, Great Peter-street, Westminster, S.W.; F. O. Mills, 31, Lansdowne road, East Croydon; L. Romero, 2, Norwood-villas, Waterworks-road, Edgbaston, Birmingham; H. W. Taylor, 8, Elphinstone-road, Avenell-road, Highbury, N.; W. B. Thompson, Ewhurst, Hendon.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

MUNICIPAL UNDERTAKINGS AND INCOME TAX.

Income tax was in the first place imposed as a temporary expedient to raise money urgently needed; it has, however, become a permanent institution without much tendency to shrink in poundage. If municipal undertakings are to be looked upon as profit-making concerns, such undertakings will have to pay income tax. Before discussing this phase of a professedly difficult problem, we must once again revert to the opinions previously put forward in these columns. We have urged that no very great difficulty ought to be found in classifying the work to be carried out by municipalities. There is one class of work not containing many items, about which there is no contention as being best carried out by the local authority. Another class with extensive items is well outside their sphere of operations. The third and smallest class consists of items either on the border line, and debatable as to which of the other classes they belong, or whether to be undertaken or not according to questions of expediency. Another point is that no municipal undertaking whatsoever should be carried on in order to obtain a profit. We feel perfectly certain that municipal profit-making is wrong in principle and will prove wrong in practice. The father of a family does not play off some of the members of the family against the others. The municipality is a family, its council the city fathers; yet these fathers seem lately to forget their fatherhood, and to differentially treat their children. But our desired Utopia is not yet, and meanwhile "profit-making" is a rampant certainty. It is but just, then, say the Income Tax Commissioners, that "profits" should bear income tax. "But," say some of the municipal wranglers, "these are really not profits. The money may be called profit, but that is really a euphemism to mislead the ignorant ratepayer, and to induce him to vote for us, who, on paper, seem to be doing so much for him." "What we do," say these sophists, "is to differentially rate the ratepayers. Those of the householders who deal with us pay a little more for their goods than they ought in justice to pay, and this extra payment is redistributed both to those who do deal with us and those who do not, thereby making our customers pay part of the rates that should legitimately fall upon non-customers. There is no income tax levied upon rates, hence there should be no income tax levied upon our profits." Unfortunately, the Income Tax Commissioners will not listen to this sophistry, but demand their pound of flesh. Under these circumstances, the poor municipalities have to pay; and their trouble is to pay as little as possible, while the Commissioners, having no bowels of compassion, are somewhat exorbitant in their demands. Assuming that the undertakings carried on by the municipalities are purely business concerns, how ought they to be taxed? To answer this question, let us first consider some of the features of municipal finance. A year or two ago some of the seaside townships had to consider the building of temporary hospitals, and in some cases applied to the Local Government Board for powers to borrow and repay the outlay over a short period

Digitized by Google

of years. Such powers to repay were almost without exception refused. Again, during the past few years large sums have been borrowed for improving the streets and paving with wood, etc. It is permitted to borrow and repay over a term, but the term of repayment is decided by the probable life of the material to be used for paving. If a seven years' term for repayment is granted, it is because the material is expected to last for seven years, and not to require replacing till after that time has passed. We may be sure that a Government office does not err in granting too long a period; indeed, all the critics we have heard indicate that the period allowed is too short. It has always seemed to us that this compulsory periodic repayment as regards municipalities served in place of depreciation and reserve in the case of companies. Income tax is not levied upon depreciation, and if one Government department says depreciation must be so much, and will not hear a whisper to the contrary, and will not extend the time for repayment—which, of course, would lessen the annual account for depreciation—surely another Government department can hardly be right when it imposes some other and less percentage for depreciation in order to increase its own bill. That is our point for the present. A municipality has no power to say what is the proper depreciation. The department decides that, and yet, we believe, another department not infrequently steps in and says, "Tommy rot. The depreciation we allow is 'so and so,' and you must pay up." This is a sample of the business-like capabilities of Government departments. Of course, there is no logic in the system. You pay all the same.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE BRITISH ELECTRIC STREET TRAMWAYS COMPANY, LIMITED.

SIR,—In one of the London evening papers of the 27th inst. there are remarks in an article relating to the prospectus issued by the British Electric Street Tramways Company, Limited, coupling the name of Thomas Parker, Limited, with that company. We beg to say Thomas Parker, Limited, has nothing whatever to do with the British Electric Street Tramways Company, Limited, and has no interest whatever in its promotion. We should be obliged if you would publish this letter to avoid any misapprehension.—Yours, etc.,

H. AND J. E. UNDERHILL AND THORNEYCROFT,
Solicitors to Thomas Parker, Limited.

24, Darlington-street, Wolverhampton, Nov. 28, 1900.

LONDON COUNTY COUNCIL TRAMWAYS.

At the meeting of the London County Council held on Tuesday last, the plans of Prof. A. B. W. Kennedy for three sections of tramlines came up for approval. The sections in question are those tramway routes between Westminster Bridge-road and Upper Tooting, between Kennington Park-road at its junction with Kennington-road and the terminus in Blackfriars-road, and between St. George's-circus and the terminus in Waterloo-road. According to the regulations of the London County Tramways Act of 1900, a certain routine has to be gone through before electricity can be used as the motive power on the lines within the county of London. For instance, the approval of the Board of Trade to the system which is to be used has to be obtained. Before this consent can be given, the road authority has to have an opportunity of being heard, so that any objections this authority may have may receive the due consideration of the Board of Trade. On Tuesday last three resolutions were passed by the London County Council. The first approved of the system devised by Prof. A. B. W. Kennedy, the next authorised the Council to submit to the Board of Trade the requisite plans and description of the system of electric traction proposed to be used, and the last resolution was to the effect that the same description and drawings were to be supplied to the Councils of the metropolitan boroughs of Lambeth, Southwark, and Wandsworth. These plans are up to the present not to be made public, but we are quite sure that such an eminent engineer as Prof. Kennedy will have devised a system which will safeguard the other users of the public streets. This being the case there should be little delay over obtaining the formal consents of the local authorities and of the Board of Trade. In such a large matter as the conversion of the whole of the London county tramways to electric traction it is well not to hurry the engineer responsible for the construction at first, but we trust that when the system has been approved and tried the conversion of the rest of the sections will be proceeded with as a matter of extreme urgency. Electric trams through the streets of the London suburbs will, of course, play havoc with the traffic of a number of suburban railways. The loss of income which will occur in this way will do more to wake up the control of these lines to their defective service than anything we know of. The record of what has been done in Sydney by electric traction is worthy of careful study by our London county councillors. When one considers that one section of the tramways in Sydney successfully carries 70,000 passengers per day, the possibilities of our London lines will be realised.

OPENING OF THE BECKENHAM ELECTRIC LIGHT STATION.

On Thursday the 22nd inst., was witnessed the opening ceremony of the electric lighting station and dust destructor works at Beckenham, the company present including members of the Urban District Council, many leading residents, and a good sprinkling of ladies. The station was open for inspection prior to the ceremony, and very great interest was taken in all that was to be seen.

Mr. T. C. COLE, J.P., chairman of the Urban District Council, presided over the opening proceedings, and after a few preliminary remarks he called upon Mr. W. H. Lendon, the chairman of the Electric Lighting Committee, to explain what, he said, was undoubtedly the most important enterprise which they as a Council had yet undertaken.

Mr. LENDON then gave a mass of information respecting the inception and carrying out of the scheme, in the course of which he pointed out that the electric lighting provisional order was bequeathed to the Council by the old Local Board. It was obtained in 1893 on the strength of a report from Mr. Gisbert Kapp, the eminent electrical expert. He referred to the decision of the Council to combine with the scheme a dust destructor, and commended their action in keeping the scheme in their own hands, and thus preventing the creation of a private monopoly, which would prevent the ratepayers from ever deriving any benefit that accrued. The total cost of the scheme was estimated at £37,000, and the Local Government Board's sanction to a loan was obtained on June 5, 1899. He traced the subsequent course of events, and specially referred to the tender from the British Insulated Wire Company as most advantageous. The main feature of this tender was, he said, that whilst the Council should erect the station and provide the electrical plant, in accordance with other tenders accepted, the British Insulated Wire Company would, at the completion of the works, take over and work the undertaking for a period of five years,

Digitized by Google

including the destruction of house refuse; the Council being relieved of all payments for sinking fund and interest, working expenses, and all other financial liabilities whatsoever during the said term, whilst, on the other hand, the contractors received the income accruing from the sale of the current. The installation would revert to the Council, without payment of any premium, at the end of the contractor's period of working. The advantages of this arrangement, said Mr. Lendon, were that there would be no loss to the Council during the five years, an assured income accruing to the Council subsequent thereto, and private monopoly would not be created. The tenders which had been accepted were as follows: erection of the engine and boiler house, chimney shaft, and approach roads, Messrs. Nightingale, £9,500; destructor and flues, Messrs. Horsfall and Co., £2,500; bringing the total cost of the buildings to £12,000. For the alternators, engines, and switchboard, Messrs. Fowler and Co., £6,600; three water-tube boilers, Messrs. Babcock and Wilcox, £3,300; cables, the British Insulated Wire Company, £14,400; arc lamps, Messrs. Lucy and Co., £600; crane, Messrs. Chatteris and Co., £160. The total cost of the contracts for electrical plant amounted to £25,000. Mr. Lendon alluded to the sagacity, forethought, and energy of Mr. R. P. Wilson (consulting engineer), Mr. A. J. Hedgcock (resident engineer of the British Insulated Wire Company), Mr. J. A. Angell (the Council's engineer and surveyor), and Mr. Fredk. Stevens (clerk to the Council). Concluding his statement, he said the electrical system adopted was that known as the high-tension alternating system, current being generated at the station at 2,000 volts and transformed to 400 volts at the various transformer stations, whence it was conveyed by low-tension distribution on the three-wire system to the houses at a pressure of 200 volts. Forty-two miles of lead-covered cables, protected by stoneware troughs filled with bitumen, had been laid in 18 miles of trenches, and 16 arc lamps would be placed in the High-street. He said the future prospects of the undertaking were most promising.

After a short interval Mrs. Cole, wife of the chairman of the District Council, switched on the light amidst the cheers of the company, and this part of the proceedings then terminated.

Later in the evening the chairman of the Council and the chairman of the Electric Light Committee entertained their brother councillors, officials, and others at a dinner at the Public Hall, Mr. T. C. Cole presiding, and among the visitors were Mr. H. W. Forster, M.P. (Sevenoaks division of Kent), Mr. G. E. Dodson, J.P. (chairman of the Penge Urban District Council), and Mr. T. Davis, J.P. (chairman of the Bromley Urban District Council). The tables were brilliantly illuminated by the electric light.

The toast of the evening, "Success to the Beckenham Lighting Undertaking," was proposed by Mr. LENDON in one of his characteristic speeches, in the course of which he said it should be known that the ratepayers were indebted for the successful inauguration of the scheme to the ability, unflagging energy, and astuteness of those who had advised them.

Mr. R. P. WILSON, the consulting engineer, replied. He said that in the early days of the consideration of this scheme, Mr. Angell and he concluded that it would be a safe estimate to put the total number of lamps connected with the main as being 11,000, or thereabouts. As a matter of fact, before long there would be 7,000, and at the end of 12 months this would increase to 12,000. But the unfortunate part was that these 12,000 represented approximately a 500-h.p. station, whilst their station was only equipped with a 400-h.p plant. The refuse destructor was really the most interesting part of this combination. The difficulty was to ascertain the calorific value of the refuse, because no two samples of refuse gave the same results.

Mr. J. A. ANGELL also replied, and in the course of his remarks said that many people had thought the Council were much too precipitate in this matter. Having regard to the fact that they had had the electric lighting order for something like seven years, and there were outside companies trying to obtain the order, and that they were informed that the Board of Trade would revoke the order if they did not make a move, he thought that this charge fell to the ground. They had no sooner started the work than people said they were exceedingly slow. But during the 15 months the work had been started they had, by an arrangement with Bromley, given Shortlands and South Hill the electric light. The Council had also introduced a dust destructor, and provided the remainder of the district with the electric light. In addition, they had solved the very difficult problem of free wiring, which was one of the finest schemes ever presented by a district council of this country. Having regard to the fact that this was done without any charge on the rates, with an assured income at the end of five years without bartering their birthright one jot or tittle, he thought there was very little in this charge that they had been slow.

Mr. A. J. BAKER, J.P., proposed "The Visitors," to which Mr. H. W. FORSTER, M.P., replied. Dr. RANDELL proposed "The Health of Mr. F. Stevens" (clerk to the Council), and that official responded in a fitting speech. Mr. A. GURNEY SMITH gave "The Hosts," and the replies of Mr. COLE and Mr. LENDON terminated the programme.

Some capital musical selections were rendered during the evening. It may be mentioned that the artistic arrangements of the electric lighting of the dinner tables had been carried out by Messrs. Buchanan and Curwen in the space of a few hours.

ON THE SUPERSESSION OF THE STEAM BY THE ELECTRIC LOCOMOTIVE.

BY W. LANGDON, VICE-PRESIDENT.

Probably one of the most interesting questions associated with the application of electrical energy to railway work, is its eventual supersession of the steam locomotive. Electric locomotives of a capacity equal to that of the steam locomotive, doing similar work, and possessing certain marked advantages, are an accomplished fact, and to many it may seem that the days of the steam locomotive are numbered. We must not, however, forget that that which has been done has its *raison d'être*. Its employment has hitherto been generally confined to localities where the effects of steam and smoke would exercise a baneful influence. Because it has been so employed, and its employment has been attended with such marked success, it does not follow, however much it may appear desirable, than in overland lines of railway electricity will in future prove to be the element of power. Railways are commercial undertakings, in which vast sums of money have been embarked, all of which, investors expect, will produce a certain annual return. The supersession of the steam by the electric locomotive thus resolves itself, primarily, into one of profit and loss. If its adoption will enable railways to be worked more economically than is the case under steam, then it will, with its attendant advantages, sooner or later, be adopted—if not by the whole, certainly by the greater portion of the railways of this country; but, whatever the ulterior advantages may be, unattended by this result, its adoption will remain doubtful.

The first question to be asked is: Are we in a position to consider the subject? Are the data at our disposal such as to admit of a reasonable treatment of it? I think we are. The primary factors are well known. We know how many pounds of steam we can obtain from a given quantity of coal. The efficiencies of prime movers and electrical generators, the loss in transmission, transformation, and distribution are all determinable. Any advantages yet to come must be looked for in the steam generator and in the simplification and consequent ultimate increase of efficiency in the electrical apparatus. In each, no doubt, the future will see production cheapened. Labour may advance, but competition will grow, and in the price of the manufactured article we may reasonably look to the future to produce some advantage. Having then the material at hand, it is reasonable to conclude that the consideration of the subject can only be attended with good; for if it should be shown that advantage is to be anticipated from such a change, it will help us to grasp that which has to be attempted, and perhaps to evolve from the data at our disposal the course most desirable to follow.

The railways of the United Kingdom comprised on Dec. 31, 1899, the following mileage of line: double line or more, 11,977; single line, 9,723—total mileage, 21,700. The number of locomotives employed for working these railways was 20,461. The total number of vehicles of all descriptions was rendered as 752,930. The year's cost for locomotive power, including stationary engines, was £16,491,377. The number of miles

* Paper read before the Institution of Electrical Engineers, Nov. 29.

travelled by trains was 396,241,265. Number of passengers, exclusive of season tickets, 1,106,691,991. The tonnage of minerals, 296,611,190; and of general merchandise, 117,011,835.

In dealing with a question of this nature it seems desirable to produce these figures; but they are, in fact, except to afford some idea of the magnitude of the subject, of very little use. The length of the passenger journeys is not stated, nor are the journeys taken by season-ticket holders included. To be of value the per passenger mileage, including, of course, the journeys made by season-ticket holders, should be given. The same objection applies to the mineral and goods tonnage statement. It records the tonnage declared as placed upon the railway, but whether it is carried one mile or one hundred miles is not shown. In fact, the returns as rendered aid the consideration of the subject very little, and I am sorry to say the information in the hands of the railway companies themselves carries us no further. Under these circumstances, the establishment of a common basis upon which to consider the relative cost presents much difficulty. The only manner in which it can be approached is by averaging the data obtainable, or by examining the work of a particular section of line. In Table I. I furnish extracts from the Board of Trade return for the year 1899, showing the mileage of line, cost of locomotive power, train mileage worked, etc., for England and Wales, Scotland and Ireland, together with certain deductions therefrom applicable to these results, as also similar data in reference to six of the most important English companies. In considering the mileage of line quoted, it should be mentioned that the figures do not disclose the *mileage of roads*. Over many sections of the several lines of railway there are more than two roads. Most main routes working out of London possess four and even six roads for a considerable distance; and the same applies to other busy portions of the chief railway systems. The table indicated shows that the cost of locomotive power for the United Kingdom, including stationary engines for pumping and other purposes, works out at 9·988d. per train mile; that the cost for England and Wales is 10·253d.; for Scotland, 8·862d.; and for Ireland, 8·104d.; and that this cost varies with the several companies quoted as follows: London and North-Western, 9·477d.; London and South-Western, 9·844d.; Great Northern, 9·892d.; Great Western, 9·905d.; Midland, 10·218d.; and North-Eastern, 12·266d.—their average cost being 10·267d. Column *l* indicates the number of trains per mile per hour, based upon the mileage of line of railway shown by the returns. Bearing in mind that there are, over many portions of the railways indicated, several lines or roads, the number of trains travelling per mile per hour is, perhaps, surprisingly small. Ireland claims but 0·615; Scotland, 1·609; England and Wales, 2·505. Of the railways individualised, the Great Western has an average of but 2; the London and South-Western and the North-Eastern each 2·2; London and North-Western, 2·9; Great Northern, 3·3; and the Midland, 3·7 (that is, the Midland, for instance, has on an average 3·7 trains passing over each *mile of line of railway* each hour, not that the mile of line is occupied by these 3·7 trains during the entire hour, but that that is the average number of trains worked over the mile of line of railway—quite irrespective of the number of lines of rails—within that period of time).

If trains were, in practice, so distributed, this might form a basis on which to found a comparison of cost for the entire railway system; but we know that this is not so—that trains are much more frequent on certain portions and less frequent on other portions of the lines of railway, and although it is a kind of basis affording some very interesting figures, it is not, as it stands, a practical one for the purpose in view. To effect this it is necessary to consider the work of an individual section of some line of railway; and with this view I have taken that portion of the Midland Company's main line between London (St. Pancras) and Bedford—omitting the suburban and local traffic applicable to the Metropolitan and Tottenham lines. The length of line of railway is 49·5 miles—practically 50 miles—and the number of lines of rails applicable to the traffic under consideration may be taken as four—it is not less. In order to ascertain the number and character of trains to be taken into consideration, I have obtained returns (Tables II. and III.) extracted from the block book, of those trains passing two points—Luton and Harpenden—each hour, during a day of 24 hours in the month of July, 1900, which I have summarised and classified so as to bring the subject within reasonable scope. These details are carried forward to Table IV., which forms the basis of calculation for comparison of cost for power to work the traffic indicated.

The classification adopted is necessarily somewhat arbitrary, but in its construction I have endeavoured to err on the right side—for instance, I have debited each train of its class as a loaded train, whereas some would certainly be light trains. Again I have, I believe, accorded to each their full merit of speed, although there is reason to assume that in many instances certain goods and minerals would not observe that allotted to them. From this table we get the tractive effort per train and the consequent mechanical and electrical power required to deal with *one hour's work*. The work may, and of course does, vary from one hour to another. Indeed, that is clearly shown by Tables II. and III.; for instance, the trains passing Harpenden vary per hour from 7 to 16, and Luton from 7 to 19, but the section of line chosen may be regarded as a full line, a line well occupied by trains both night and day, Sundays and weekdays. The returns show an average of 11·9 trains passing Luton and of 12·4 passing Harpenden per hour. In taking an average, however, I have apportioned no less than 14 trains to the hour. This number divided between the four lines of metals gives a result of 3·5 trains per mile per hour per line of metals. It may here, however, be as well to point out that, so long as the appropriated number of trains is fairly that in practice, the number applied is, for comparison purposes, immaterial, for the comparison I draw is based upon the train mileage cost.

Fig. 1 illustrates the section of line under consideration. The position of engine-sheds is shown by stars (*); of water-

cranes by dots (·). The short or suburban traffic between St. Pancras and Hendon, and the Tottenham line, etc., is not included in my schedules, for the reason that, viewing the section of line as if actually subject to electrical working, there would be little doubt that this immediate London-suburban traffic would demand a generating station nearer home than that indicated in the scheme I have adopted as my basis for the comparison of costs for working a 50-mile section of line. The plant scheme is roughly outlined in Fig. 2. Midway in the 50 miles of railway is the central station, containing four 2,500-kw. three-phase, or other characteristic, 10,000-volt generators. At this pressure current is distributed to sub-stations, each serving 10 miles of railway, where the potential is converted to 600, from whence it is carried to the contact rail. Or the centre 10-mile section may be provided for by direct-current generators served from the same steam plant. The efficiencies of the various parts are assumed as follows:

	Loss, per cent.	Efficiency.
Motors	15	·85
Ohmic loss in rails	10	·90
Leakage	2½	·975
Rotary converters	10	·90
Static transformers	7	·93
High-tension transmission	10	·90

The total kilowatts required on the train wheels (Table IV.) is 2,905 per hour, and the number of trains is 14. Therefore $\left(\frac{2,905}{14}\right) = 207{\cdot}5$ will be the average kilowatts per train hour; and, assuming the efficiency of the motors at 85 per cent., $\left(\frac{207{\cdot}5}{{\cdot}85}\right) = 244$ kw. will be the average power required to be supplied to each train. If, now, we allow 10 per cent. loss in the rails which supply and return the current, a pressure of 540 only will be available at either end of a section of 10 miles. Therefore the amperes per train that will be required will be $\left(\frac{244 \times 1,000}{540}\right) = 452$. As there are 14 trains per hour in the total 50 miles section, there will be $\frac{14}{5} = 2{\cdot}8$, say three trains in one section of 10 miles to be supplied by one sub-station,

$$452 \times 3 = 1,356 \text{ amperes.}$$

Adding 2½ per cent. for leakage, we have 1,390 amperes as the current to be supplied by each sub-station at 600 volts. The efficiency of the converters and static transformers is taken at, respectively, 90 per cent. and 93 per cent., and the three-phase transmission at 90 per cent. $\therefore \frac{1,390 \times 600}{1,000 \times {\cdot}9 \times {\cdot}93 \times {\cdot}9} = 1,107$ kw. to be delivered to the trains for each section containing three trains. As there are 14 trains there will be four sections with three each, and one section with two trains. Now the four sections with three trains each would require $1,107 \times 4 = 4,428$ kw. To allow for the maximum loss let it be assumed that the centre 10-mile section, which, as previously indicated, might be supplied direct at 600 volts, is so dealt with, and that it is the section that has two trains only. The kilowatts required would equal

$$\frac{1,390 \times 600}{1,000} \times \frac{2}{3} = 556 \text{ kw.}$$

Therefore, the total kilowatts to be generated would be—

$$(4,428 + 556) = 4,984, \text{ say } 5,000,$$

and the combined efficiency $\left(\frac{2,905}{4,984}\right)$ would be 58·3 per cent.

This 5,000 kw. is the power required to be generated to work the 14 trains, travelling 479 miles during the hour, as shown in Table IV., and upon it all comparative calculations and deductions have to be based.

The demand may, of course, go beyond this, or it may be less, but so long as the generating power, and that of the corresponding parts, is there to meet it, that branch of the question may be disregarded. As I have previously stated, the comparison is made between the ascertained quantities travelling a stated mileage at a stated speed. If the mileage were greater, or the number of trains greater, the comparison would be equally applicable. It is in respect of the mileage result immaterial, so long as we apply it to a fairly representative condition. The speed and the train load indicated in Table IV. will, I believe, bearing in mind that the number of trains are regarded as all carrying the full load indicated, be found to conform to this. A generating plant capable of an output of 10,000 kw. is, of course, ample to provide for a calculated demand of just half that amount. I adopt the following estimate as applicable to the prime cost.

Digitized by Google

TABLE IV.—Basis of Calculation.—Showing Number of Trains, classified, passing certain points of a 50-mile Section of Line of Railway; Calculated Mechanical Horse-power and Electrical Power for working the same, together with apportioned Speed, Load, etc.

Class of train.	Number of trains per day of 24 hours passing.		Basis of calculation.							Total.	
	Luton.	Harpenden.	Apportioned number of trains per hour	Speed, miles per hour.	Train-miles per hour.	Load, including engine, tons.	Total tractive effort per train.*	Mechanical horse-power per train hour.	Equivalent in kilowatt hours.	Mechanical horse-power per hour.	Equivalent in kilowatts per hour.
1. Express passenger	62	67	3	50	150	275	3,575	477	356	1,431	1,068
2. Ordinary passenger and empty coaches	36	41	2	32	64	300	2,130	182	136	364	272
3. Express goods and perishables	74	78	4	35	140	400	3,160	295	220	1,180	880
4. Ordinary goods and minerals	115	111	5	25	125	500	2,750	183	137	915	685
Totals	287	297	14		479					3,890	2,905
Average per hour	11 9	12 4									

Tractive effort per ton $= 3 + \frac{V^2}{250}$ where V = speed in miles per hour. Horse-power $= \frac{\text{Tractive effort pounds} \times \text{miles per hour}}{375}$

* Tractive effort × load tons = total tractive effort per train.

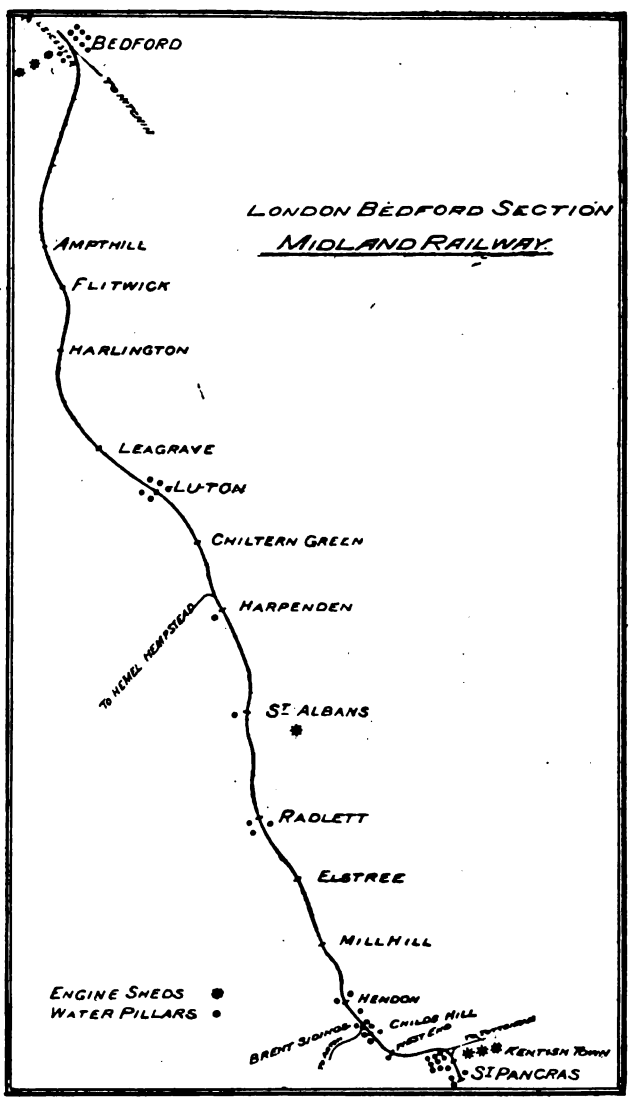

Fig. 1.

Generating Station.		
Buildings, foundations, chimney stacks, etc. ...	£50,000	
Equipment, including steam units, boilers, coal conveyers, steam mains, condensers, pumps, etc.	200,000	
		£250,000
Sub Stations.		
Buildings—five stations.....	10,000	
Equipment of ditto with transformers, converters, etc., delivering at 600 volts, and all necessary fittings.....	70,000	
		80,000
Cables, including laying.....	70,000	
Contact rail, 200 miles—*i.e.*, four roads of 50 miles each.....	70,000	
		140,000
Total capital outlay for generation and distribution of current.....		£470,000

The figures comprised within the two first items are practically those given by Mr. Parshall with reference to a somewhat similar plant, with the exception that the amounts have been increased to the extent of £15,000 for the generating station equipment, consequent upon the adoption of a higher voltage; and £10,000 for generating station buildings to meet any advance of prices; £10,000 has also been added for independent transformer buildings. The cost of cables,

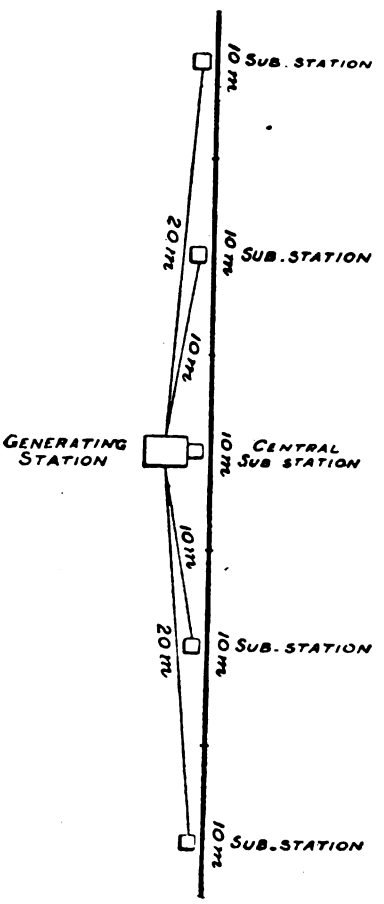

Fig. 2.

including laying in position, is based upon the current demand and mileage. The hourly demand has been shown to be 5,000 kw. The annual output for the section of line under consideration will therefore be this amount multiplied by the 24 hours per day, and 365 days to the year—viz., 43,800,000 kilowatt-hours. On this basis I estimate the annual cost for generation and distribution of current as shown in the annual column of the following table, from which, by dividing the sums there shown by the annual kilowatt output, I obtain the per kilowatt-hour charge. To the foregoing we have to add the cost for drivers and assistants in attendance upon the electric locomotives—performing practically the same duties as the driver and firemen in attendance upon the steam locomotive, together with that for repair and renewal of all machinery, including the locomotives.

(To be continued.)

LIGHT RAILWAYS.

Notices of intended application under the Light Railways Acts, 1896, have appeared in the *London Gazette* as follows: Bridlington and Fordingham Light Railway Company (extension of time, etc.), Rotherham, Tindsley, and Tickhill light railway (promotion by company), Tannock Valley Light Railway Company (extension of time, etc.), Mitcham light railway (promotion by the Croydon Rural District Council), Dartford light railways (promotion by the Urban and Rural District Councils), Halesowen light railway (promotion by the Rural District Council), Sandgate, Cheriton, and Folkestone light railway (promotion by company), Potteries light railways (extension), Isle of Thanet light railways (extension of time), Pwllheli, Nevin, and Porthdinlleyn light railways (promotion by North Wales and District Light Railway and Electric Power Syndicate), Worcester light railways (extension), Warrington and Northwich light railway (promotion by company), Barton-upon-Irwell (promotion by Rural District Council), Rhondda Valley light railway (extension and wideninga), Mid-Suffolk light railway (promotion by company), Lizard light railway (extension of time).

The Works Committee of the Beckenham Urban District Council are considering the proposed electric railway or tramway for the purpose of improving the communication between Beckenham, the Crystal Palace, and the town of Croydon.

Permission has been granted by the Chester-le-Street Highway Authority to the United Kingdom Tramways and Light Railway Syndicate to build an electric tramway connecting the Hettons by way of Houghton-le-Spring, Newbottle, Painshaw, Washington, Washington New-road, now in course of construction, with Gateshead and Tyneside.

The proposal to form a light electric railway connecting the village of Lyndhurst with Lyndhurst-road Station has so far progressed that application will be made in the ensuing session of Parliament for the necessary powers to carry out the project. The proposed railway would pass almost exclusively over forest land.

There appears to be some prospect of the Derby and Ashbourne light railway project being proceeded with, preliminary difficulties and differences concerning the mode of construction of the rails within the borough having been tentatively, at all events, settled.

The Commissioners have submitted to the Board of Trade for confirmation the Brackenhill light railway order.

The Basingstoke Town Council have decided to grant an interview to representatives of the promoters of the proposed light railway from Basingstoke to Kingsclere.

The Dartford district light railways order came before Sir Courtenay Boyle at the Board of Trade on Tuesday. The order was practically agreed to in 1897 by the Light Railway Commissioners subject to the promoters giving a satisfactory access to the Thames. In 1899 the promoters after a local enquiry satisfied the Commissioners on this point, and the order was subsequently sent to the Board of Trade for confirmation. In 1898 Messrs. Burroughs, Wellcome, and Co. bought some of the scheduled property, which they converted into a recreation ground for their workpeople—between 1,100 and 1,200 — at Dartford, but they had not been informed of the scheme, and only discovered subsequent to the local enquiry that the proposed railway would cut their newly laid-out recreation ground into two. It was urged that the Commissioners ought not to hang up a scheme for two years and then amend it without giving notice to all the parties then affected. Sir Courtenay Boyle said no time limit was imposed upon the Commissioners, and at his suggestion the parties are to meet in conference and try to arrange the matter. The promoters' engineer suggested the construction of a light iron viaduct to carry the railway over the recreation ground.—*The Times.*

The proposed North-Eastern Railway Bill contains the following paragraph: "Power is sought . . . to provide for the vesting of the undertakings of the Isle of Axholme and Goole and Marshland Light Railway Companies (hereinafter called 'the light railway companies') in the company upon such terms and conditions as have been or may be agreed upon, or as may be prescribed by the intended Act, and to provide for the dissolution of the light railway companies and for the exercise and fulfilment by the company of all the rights, powers, privileges, liabilities, and obligations of the light railway companies, and to confirm any agreement made between the company and the light railway companies or either of them in anticipation of or relating to any of the objects of the intended Act." The company will also apply for powers to acquire the powers granted for a light railway from Haxey, through Bawtry to Tickhill, thus connecting the Isle of Axholme and Goole lines with the South Yorkshire coalfields.

The Crewe Town Council are about to make application to the Commissioners for an order to carry out a scheme of light railways in the borough, which will be worked in connection with the electric light undertakings. The scheme involves eight railways. The proposed gauge is 3ft. 6in., and it is estimated that the power for the traction can be supplied from the present electric plant.

FORTHCOMING EVENTS.

FRIDAY, NOV. 30.

Institution of Junior Engineers.—At 8 p.m., at Westminster Palace Hotel, inaugural meeting of twentieth session. Presidential address by Sir Lowthian Bell, Bart., F.R.S.

The Faradian Club.—At 8 p.m., at 8, Charing Cross-road. Lecture on "Swiss Polyphase Railways," by Prof. C. A. Carus-Wilson.

SATURDAY, DEC. 1.

Institution of Electrical Engineers.—At 2 p.m. and 3 p.m., students' visits to the generating station of the Waterloo and City Railway.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., ordinary meeting. Paper on "The Overstraining of Iron," by Mr. Jas. Muir.

MONDAY, DEC. 3.

Institution of Electrical Engineers.—Annual dinner at Hotel Cecil, at 7 for 7.30 p.m.

Institution of Electrical Engineers (Newcastle-on-Tyne Section). At 8 p.m., ordinary meeting at Durham College of Science.

Liverpool Self-Propelled Traffic Association.—At 8 p.m., at Royal Institution, "Heavy Motor Traffic in France," by Mr. G. Forestier.

TUESDAY, DEC. 4.

Society of Arts.—At 8 p.m., Cantor lecture on "Electric Oscillations and Electric Waves" (lecture II.), by Prof. J. A. Fleming, F.R.S.

Institution of Civil Engineers.—At 8 p.m., paper on "Machinery for the Manufacture of Smokeless Powder," by Mr. Oscar Guttmann. Other papers to be read, time permitting, "The Signalling on the Waterloo and City Railway," and "Note on the Signalling of Outlying Siding Connections," by Mr. Alfred Weeks Szlumper; "Signalling on the Liverpool Overhead Railway," by Mr. Stephen Butler Cottrell.

WEDNESDAY, DEC. 5.

Institution of Electrical Engineers.—At 7.30 p.m., at 28, Victoria-street, students' meeting. Papers on "Bipolar Machines at the Paris Exhibition," by Mr. R. L. Pearson and "Direct-Current Multipolar Generators at the Paris Exhibition," by Mr. C. T. Stephenson.

Society of Arts.—At 8 p.m., paper on "Road Traction," by Prof. H. S. Hele-Shaw.

THURSDAY, DEC. 6.

Institution of Electrical Engineers.—At 8 p.m., probable extra meeting at Institution of Mechanical Engineers to discuss the paper on "The Supersession of the Steam by the Electric Locomotive," by Mr. W. E. Langdon.

Rontgen Society.—At 8 p.m., at 20, Hanover-square. Exhibition and description by Mr. J. Mackenzie Davison, M.B., of his stereoscopic fluoroscope and a new rotary mercury break.

Civil and Mechanical Engineers' Society.—At 8 p.m., at Hotel Victoria. Paper on "Valve Gears and Valve Diagrams," by Prof. R. H. Smith.

FRIDAY, DEC. 7.

Institution of Electrical Engineers.—At 4 p.m., students' visit to the Electrical Standards Laboratory of the Board of Trade, 8, Richmond-terrace, Whitehall (see front note).

Faradian Club.—At 8 p.m., at 8, Charing Cross-road. Lecture on the "Modern Steam Engine," by Mr. J. S. Raworth.

Institution of Civil Engineers.—At 8 p.m., students' meeting. Paper on "Dock Gates," by Mr. F. K. Peach.

SATURDAY, DEC. 8.

Institution of Electrical Engineers.—Students' visit to the Manchester-square Station of the Metropolitan Electric Supply Company.

Institution of Junior Engineers.—Visit, at 3 p.m., to the electric generating station of the London Electric Tramway Company, 88, High-road, Chiswick.

NEW COMMITTEES.

The following additional committees have been appointed:

NORWICH—*Tramways:* Messrs. R. G. Bagshaw, G. M. Chamberlin, C. Cunnell, G. Green, W. H. Hackblock, D. Havers, A. C. Havers, J. Moore, G. White, M.P., and E. Wild.

ROCHDALE.—*Tramways:* Councillor Duncan, chairman.

ST. PANCRAS—*Electricity and Public Lighting*: The Mayor; Aldermen W. Smith, M.D. (chairman), E. Cox-Sinclair, H. G. Regnart, and N. Robinson, L.C.C.; Councillors G. A. Hodgkinson (deputy chairman), W. Barnard, F. B. Cameron, E. M. Close, J. Dean, J. Gauntlett, Dr. W. F. Hazel, G. Hickling, T. H. W. Idris, J.P., L.C.C., J. Johnson, Dr. R. Paramore, G. B. Shaw, G. P. Thomson, J. Thornley, J.P., W. H. Walkley, and T. D. Woodhouse.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

329. Describe and explain what you consider the best workshop method of determining the values of B and H, and for plotting B and H curves of wrought iron and steel.—A. F. W.

330. When feeding boilers with very soft feed water, in which there is a good deal of peat acid, what kind of feed pipes would you recommend (1) taking the outlay into consideration, (2) disregarding outlay altogether?—C. H. K.

ANSWERS.

Question No. 323.—In alternating-current supplies with networks of concentric cables, in switching on and off there is a danger of breakdown in the insulation between the outer conductor and the lead covering. What is the best way to prevent this defect?

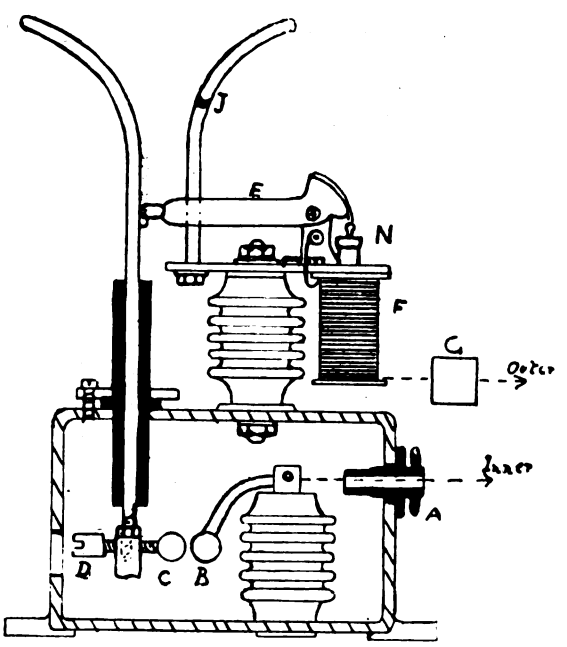
Best Answer to No. 323 *(awarded* 10*s.)*.—In order to deduce the precautions necessary to reduce to a minimum the risk of breakdown of the insulation between outer and lead on a concentric main, it is necessary, first of all, to investigate the probable cause of such breakdowns. The subject is a large one, however, and within the scope of the present answer it is only possible in some cases to state conclusions without fully tracing out the reasoning leading thereto.

Consider the case of a system of concentric feeders supplying transformers at a considerable distance from the generating station, and let us assume that through some cause or other the outer of one of the feeders is disconnected at the station end, whilst its inner remains connected to the inner 'bus bar. The cables may be considered in a sense as condensers, the dielectrics of which are the insulations between outer and lead. Let the capacity between the disconnected outer and the lead sheathing be called C_1, and the sum of all the capacities of the connected cables between outer and lead be called C_2. Now the disconnected outer prevents the current returning to the outer 'bus bar in the usual manner; nevertheless, a current will flow, its course being from inner 'bus bar, through inner conductor and primary of transformer to outer conductor, and through C_1 to lead (or earth), from thence to the lead of all the other cables, returning to the station outer bar *vid* C_2, and the other outer conductors which are connected to the bar at the time. In this case C_1 and C_2 are in series, but if the number of feeders is large, C_2 will be large enough to justify us in considering all these outer conductors as directly earthed, so that C_1 is the only capacity to be dealt with, and the insulation around the disconnected outer will have to stand the full voltage of the capacity current. If this voltage were never greater than the station voltage, the outer insulation would probably be able to stand the stress. We cannot, however, rely on such being the case. The transformer may for our purposes be considered as merely part of the circuit, possessing resistance and a variable amount of self-induction, and it is a well-known fact that when a capacity and inductance exist in series a resonance occurs between them which under certain circumstances has the effect of raising the voltage to two or three times its normal value. This, in the case in question, would mean an inevitable breakdown.

Each value of self-induction in the transformer produces a maximum rise in voltage in conjunction with a certain definite capacity, and the capacity varies with the length of cable. Above and below this certain length of cable the pressure rise becomes less and less. If the secondary of the transformer has a non-inductive load, the self-induction of the primary will be comparatively small, and in this case the length of cable which would produce a maximum rise will be rather a short one, but the rise itself will not be great. On the other hand, should the load be highly inductive, the most dangerous length will be considerably greater, and voltage rise also much greater. With the secondary on open circuit, the values to produce the maximum effect lie in between those of the two cases just quoted, and will be dependent on the design of the transformer. In either case breakdowns might occur, and to obviate them the following rules must be adhered to: close the outer switch first; open the outer switch last; avoid all fuses in the outer circuit, or if fuses are inserted make them heavy enough to ensure the inner fuse blowing first; earth the outer conductor at one point. Modifications of the above cases occur, but which space will not permit me to deal with. The same rules, however, may be effectively applied in these cases also. If the cables are very long and of high capacity, and the voltage extra high, say 5,000 and above, additional precautions are found advisable, for dangerous surgings result if the cable is switched in in the usual manner, accompanied by a rise in pressure.

To avoid a breakdown: (*a*) gradually load the feeder up instead of suddenly switching in; (*b*) make use of an apparatus for automatically preventing an undue rise of pressure in the mains.

(*a*) This end is accomplished at Willesden by first connecting the cable to be made alive to the high-tension 'bus bar in series with the primary of a small transformer, the secondary being on open circuit. The self-induction of the primary is now so great that practically no current can flow, a water resistance is now inserted in the secondary circuit, and the plates are gradually brought closer and closer together until finally the winding is short-circuited. When this occurs the self-induction in the primary is so small that it also may safely be short-circuited, and the transformer cut out, leaving the feeder directly connected to the 'bus bar. By this means any sudden rush of current in the cable is avoided.

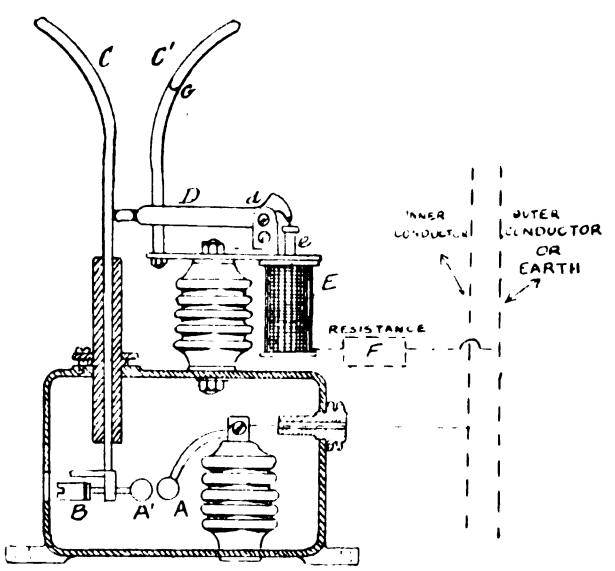


(*b*) The figure is a sketch of a "Partridge" mains discharger, and is in use, I believe, at Willesden and Deptford. A connection from the inner conductor is brought to the insulated ball, B. C, a similar ball (whose distance from B may be regulated by the screw, D), is in connection with the outer conductor through the pivoted arm, E, the solenoid, F, and the resistance, G; H is an iron plunge connected by means of a chain with the arm, E, in such a manner that when H is drawn down E rises, breaking the circuit; J is a stop, which limits the travel of the arm,

Digitized by Google

E. Now, the distance between the balls, B and C, is so adjusted that when for any reason the voltage of the main rises 25 per cent. above the normal, a spark passes across the air-gap which separates them, and the discharge which follows, having to traverse the windings of F before reaching the outer, causes it strongly to attract H, which in turn moves E, thus producing a second break in the circuit. The arc thus formed rises with E, and when E reaches J continues upwards, and finally dies away at the tips of the curved arms. Immediately the arc ceases E falls by gravity into its original position, and remains there until a further rise in pressure occurs. This arrangement has been found most effective in preventing breakdowns due to surges set up in the feeder, from any cause, which might otherwise have caused much trouble.—W. G. M.

Answer to No. 323 (*awarded* 5*s.*).—On first glancing at the question speaking of alternating-current networks, one is inclined to suppose, by networks, that low-tension cables are the subject of the question; if so, it is a very unusual occurrence for a low-tension cable to break down between outer and earth, as the pressure would not be above 250 volts, and the inductive effect at the voltage would not be sufficient to break down a paper-insulated lead-covered cable. If the cables are subjected to a thorough test, say at 1,000 volts, for one hour when laid, there need be no fear under ordinary circumstances of them breaking down when switching on or off the load. If the conductivity of the lead covering is not efficiently maintained at sub-stations, joint-boxes, etc., and the whole thoroughly earthed, the faults may be due to the proximity of electric traction using the earth as a return; this might attack the lead covering, and by electrolysis get through the lead, causing a weak spot, so that when current was switched on or off the mains the cable would break down at these places. The question is more applicable to high-tension networks feeding transformer sub stations or house-to-house transformers, where the liability of break-down between the outer and earth has been overcome by the universal practice of earthing the outer. We still have the difficulty to overcome to prevent the inner getting to earth. The protection of electrical circuits from the effects of abnormal high pressures has been practised since the introduction of overhead wiring for telephones, electric light, etc., by means of such devices as spark gaps between two metallic horns, so constructed that the convection currents caused by the spark cause the spark to rise to where the gap is so wide that the spark is exhausted. A similar



effect caused by the effect of lightning on aerial wires is the effect caused by inductance and capacity of high-tension cables or any apparatus connected to them when any part of the circuit is connected to or disconnected from the rest of the circuit. To overcome this danger, Mr. Partridge, the chief engineer to the London Electric Supply Corporation, has brought out a very ingenious apparatus, which is manufactured by Messrs. Elliott Bros. A A is an adjustable spark-gap; the screw at B can be adjusted for any pressure. After sparking between the two balls the path of the current is up one of the metallic horns, C; C' is the other horn, the width between which increases with the height. The metallic lever, D, normally short-circuits the two horns, and it is pivoted at *d*, and on its end it carries a small iron core, *e*, which is supported at the mouth of the solenoid, E. The path of the current is through the lever, D, through solenoid, E, in series with which is a non-inductive resistance, F, thence to earth or the outer conductor. When a current flows it energises the solenoid, E, attracting the iron core, *e*, which lifts the lever, D, until it strikes the horn C' at the point, G, at which point the spark is transferred to the two horns, where the gap is wide enough to allow the convection currents to lift the flash until it is extinguished by the widening parts of the horns. This apparatus has given great satisfaction, and will efficiently discharge the cable if by any means the pressure should rise to 50 per cent. above the normal or any other percentage which may be required.—W. A. J.

Question No. 324.—Compare the cost of lighting by direct and alternating current arc lamps respectively.

Answer to No. 324 (*awarded* 7*s.* 6*d.*).—The question is asked in very general terms, and the object of the enquiry would have been best attained under the consideration of the different types for a given problem. We can, however, obtain much information by dealing with the subject generally. In the first case, let us take the lamps themselves. It is generally acknowledged, and, in fact, has been proved by experiment, that the continuous-current lamp is more economical and efficient than the alternating-current lamp. To investigate the reason of this, it will be necessary to briefly review the nature of the arc. It has been shown that in the case of the continuous-current lamp the light emitted depends on the area and temperature of the crater which is formed on the positive carbon. The temperature at the arc, which is the temperature of the volatilisation of carbon, and which is always constant, necessitates a potential difference of 39 volts; the area of the crater is proportional to the current. It will be seen that with a continuous-current lamp the voltage and current are steady; thus the arc soon attains its normal condition. What have we in the case of the alternating-current lamp, however? That the voltage is continually changing between zero and a positive or negative maximum, and alternating in direction. Applying this, it will be seen that for the greater portion of every period we have not the voltage required to strike the arc or to volatilise the carbon. Thus for a corresponding period there will be no light given from the arc. The alternations are so rapid, however, that this is not visible to the naked eye. Further, we have a constantly varying temperature, therefore a lower mean temperature. As each carbon is alternately positive and negative, a crater cannot be formed on either, as in the case of the direct-current lamp; and as the crater is the hottest portion of the arc, it will follow there will be a further tendency for the mean temperature of the arc to be lower. Another point of importance is that as 85 per cent. of the light is emitted from the positive carbon, the light in the alternating-current lamp will be thrown alternately up and down, a greater portion of the up light being lost, whereas in the continuous-current lamp the light can be always thrown down by making the top carbon the positive, or the reverse for inverted lamps. The loss in the mechanical part of the alternating-current lamp is greater than in that of the continuous-current lamp, owing to induction.

From this brief *résumé* it will be seen there are a number of reasons why the alternating-current lamp should not be so efficient as the continuous-current lamp. In the application of the lamps themselves, however, there are cases where the alternating-current system would be cheaper than the continuous-current system. Take, for instance, where a consumer is fed off the town mains with 100 or 200 volts. If he requires one lamp only, by the use of a transforming choking coil with the alternating current he can take an economical supply of either 100 or 200 volts. Care must be taken in this case, however, that he has a wattmeter installed and not a current meter, as used by most alternating stations. It is also possible to run three

Digitized by Google

lamps in series off a 100-volt supply, whereas two lamps only could be taken off a 100-volt continuous-current supply. It is questionable, however, if even in this case the alternating-current lamp would be the most economical. In the case of public lighting where the supply is on the alternating-current system, though separate mains for the continuous-current arc lighting has its advantages, under ordinary conditions, alternating current rectified would probably be the most economical. Comparative efficiencies of various types have been given by Elihu Thomson. The following are taken from the *Electrical Engineer*, Sept. 22, 1899:

POWER PER CANDLE POWER WHEN LIGHT EMITTED DOWNWARDS ONLY IS CONSIDERED.

Type of lamp.	Watts per candle-power.
Naked arc	·5
Enclosed arc	1·5
Alternating-current arc with reflector	·8
Alternating-current arc without reflector	1·12
Enclosed alternating	2·0

This table is instructive, inasmuch as it shows comparative costs for various types of lamps if the conditions for all are equally favourable. Of course, the carbon and labour items must be considered when comparing enclosed lamps with open types. In conclusion, the working of alternating-current lamps cannot be said to be as satisfactory as continuous-current lamps. Screws are found to work loose, and this may become a source of annoyance. The extra attention they require cannot be ignored when comparing the comparative costs with continuous-current lamps.—E. T. W.

Answer to No. 324 (*awarded* 7*s.* 6*d.*).—When we consider the cost of lighting by direct or alternating arc lamps, we must take into consideration (1) the capital outlay, (2) cost of supply. With direct-current arc lamps no special machinery need be installed, as the lamps may be connected nine or ten in series across the 460-volt mains. A small additional cost, amounting to about £30, for cable to connect the lamps, is about the only item specially required. The table below shows the cost of direct arcs:

Capital Outlay.

10 lamps, including spare	£80	0	0
10 lamp columns at £10. 10s.	105	0	0
500 yards cable, at 1s. 3d. per yard	31	5	0
10 isolating switches, at £2. 9s. 6d.	24	15	0
10 service boxes at £1	10	0	0
Cable laying, erecting columns	120	0	0
Sundries	24	0	0
Cost of 10 lamps	£395	0	0

Cost of one lamp, £39. 10s.

Cost of Supply.

Interest and sinking fund charges	£24	0	0
Labour, trimming, attendance, etc.	60	0	0
Energy, 10 by 920 units (at 2d. per unit)	76	13	8
Carbons	12	0	0
	£172	13	8

Annual cost per lamp, £17. 5s.

When alternating current is used, the lighting must be either supplied by means of a rectifier or else by transformer. If a rectifier is used, £373 must be added to the above capital outlay, and if transformers in the lamp columns £4 per transformer must be added, and all these items make the generating expenses more. The cost of supplying arc lamps by rectified currents was given in a paper read before the Electrical Engineers as £19, for transformers for each lamp £18. Against this, Edinburgh supplied lamps at £16 per annum. The table of charges in connection with the rectified system as running at present in one of our central stations is given below:

Capital Outlay.

Rectifiers complete (one spare)	£373	3	6
25 arc lamps (four spare)	262	10	0
25 high-tension switches, £2. 9s. 6d.	61	17	6
25 lamp columns	262	10	0
Trimming ladder	13	10	0
Arc lighting cable, at 1s. 3d. per yard	231	0	0
Erection, laying cable, etc.	288	15	0
25 service boxes at £1	25	0	0
Sundries	52	5	0
Total for 25 lamps	£1,570	11	0

Cost of Supply.

Interest and sinking fund at 6 per cent.	£94	4	7
Labour	156	0	0
Energy, 25 by 920 units at 2d. per unit	191	0	0
Carbons	30	12	6
	£471	17	1

Cost per lamp (approximate), £19.

It is claimed that with rectifiers that these lamps require no more energy than direct-current lamps and that the candle-power is higher. The cost of arc-lighting by the transformer method is given below:

Capital Outlay.

25 service boxes	£25	0	0
25 arc lamps (four spare)	262	10	0
25 columns	262	10	0
25 transformers	200	0	0
25 switches	61	17	0
1 ladder	13	10	0
Service cable, £1 per post	25	0	0
Labour	48	0	0
Total cost for 25 lamps	£898	7	0

Cost of Supply.

Interest, etc., 6 per cent.	£54	0	0
Labour, etc.	156	0	0
Generating 570 watts	217	10	0
Carbons	30	0	0
Cost of 25 arcs	£457	0	0

Cost per lamp (approximate), £18.

Thus we see from the above figures that taking each system as satisfactory the direct-current arc lamps are supplied much cheaper than alternating-current arc lamps.—F. M. M.

Answer to No. 324 (*awarded* 5*s.*).—The vital question in comparing direct and alternating current arc lamp systems is the relative amount of power consumed for a given amount of light. Much will, however, depend upon the circumstances and local conditions, for in cases where a large number of circuits have to be run for a great distance in the same street, a saving in the investment could probably be made by adopting an alternating-current system with sub-stations at the points of distribution. But in the actual comparison the different types of lamps may be classified in the following manner:

	Watts at arc.	Candle-power.
Direct-current open arc	450	2,000
Direct-current enclosed arc	450	1,500
Alternate-current open arc	450	1,150
Alternate-current enclosed arc	400	950
Direct-current open arc	300	1,200
Direct-current enclosed arc	300	900

Then, so as to arrive at an equitable figure for comparing the direct open and enclosed arcs, we may assume that the ratio of watts per mean spherical candle-power in the open arc to those in the enclosed arc is 75 per cent., as "obtained by Elihu Thomson and others." The excess of watts per mean spherical candle-power for alternating-current arcs over direct-current is approximately 33·3 per cent. The accompanying table of relative costs is on the assumption that in every case the lighting part of the plant is running at very nearly full load.—K.

TABLE OF RELATIVE COST FOR 3,800 HOURS.

Systems.	Total cost per lamp.	I H.P. per lamp	Total operating expenses.
	£ s. d.		£ s. d.
Alternating-current enclosed arc, 400 watts	28 14 6	708	10 8 6
Direct-current driven by alternate-current motor, enclosed 300-watt lamps	27 0 0	630	9 9 0
Direct-current driven by belts, 300 watts, enclosed	24 5 0	552	8 10 6
Direct-current direct-driven, 450 watts, open	29 2 0	810	12 16 0
Direct-current driven by alternate-current motors, 450 watts, enclosed	20 15 0	948	11 0 0
Rectifier system, 450 watts, enclosed	31 14 0	816	10 15 0
Incandescent lamps, three 50-c.p. lamps, 450 watts	25 0 0	766	12 0 0

Sheffield.—Electric traction was inaugurated on the Brightside route of the Sheffield city tramways on the 26th inst.

Digitized by Google

PHYSICAL SOCIETY.

At the ordinary meeting on Nov. 23, Prof. Everett, F.R.S., vice-president, in the chair, a paper on "**A Self-Adjusting Wheatstone's Bridge**," by **E. H. Griffiths** and **W. C. D. Whetham**, was read by Mr. Whetham. The object of this paper is to describe a cheap and easy method of getting a self-adjusting bridge to show on a scale the actual resistance of any wire. Contact with the bridge wire is made by means of a light horizontal bar, which is suspended by a phosphor-bronze strip from the coil of the d'Arsonval galvanometer used with the instrument. A second bar, parallel to and above the first, is rigidly connected with the coil. A wooden beam, worked by clockwork, moves up and down between the bars and clamps them alternately. When the beam is down, contact is made with the bridge wire. If this contact is not at the zero point a current will flow through the coil, and if the cell is connected up the proper way it will turn the coil so as to bring the upper bar nearer to the null point. This puts a twist into the phosphor-bronze strip, and when the beam rises and clamps the upper bar the torsion comes into play and brings the lower bar under the upper one. The beam then descends and makes contact at this point, and if any current flows through the galvanometer there is further movement until the null point is reached. Any alteration in the resistance of the wire under experiment causes a movement of the zero point on the bridge wire, and this is followed by the lower arm. The position of the lower arm can be directly indicated by means of a scale.

Prof. S. P. Thompson asked how the scale was calibrated.

Mr. Whetham said the scale was arbitrary, but it could be calibrated by the known resistance of the bridge wire per unit length. Extension of the range could be obtained by shunting the bridge wire with various resistances

Mr. Glazebrook asked how sensitive the bridge was.

Mr. Whetham said that working with a dry cell it could easily indicate 1deg. on a platinum thermometer.

Mr. Blakesley pointed out that if the cell was connected up the wrong way, the zero point would be an unstable one.

A paper on "**The Liquefaction of Hydrogen**" was read by **Dr. M. W. Travers**. These experiments were undertaken in order to provide liquid hydrogen in sufficient quantity for the separation of neon from the helium, with which it is usually mixed. The separation is effected by cooling the gases to the temperature of hydrogen boiling at atmospheric pressure. The principles and conclusions do not differ from those of Dewar, but as the production of liquid hydrogen is neither difficult nor costly an account of the experiments is given. In 1884 Wroblewski showed that strongly coiled and compressed hydrogen on being allowed to expand formed mist or spray in the tube, and later Olozweski repeated these experiments on a larger scale and determined the temperature of the liquid. Other methods of liquefying hydrogen have been suggested by Lord Rayleigh and Kammerlingh Onnes. In the case of many gases a fall of temperature takes place on free expansion, but under ordinary circumstances the temperature rises in the case of hydrogen and helium The principle of free expansion was first applied by Hampson and Linde to the liquefaction of air. Within the last two years Dewar has shown that at a temperature close to – 200deg. C. hydrogen behaves as an imperfect gas, and becomes cooled when allowed to expand. This principle has been applied by Dewar to the liquefaction of hydrogen in quantity. In the author's experiments, hydrogen under a pressure of 200 atmospheres passes through a coil which is cooled to –80deg. C. by a mixture of solid carbonic acid and alcohol. It then enters another coil contained in a chamber which is continually replenished with liquid air. The lower portion of this coil passes into another chamber which is closed, and communicates through a pipe with an exhaust pump. Liquid air flows continuously from the first chamber into the second through a pin valve controlled by a lever. The liquid air boiling under a pressure of 100mm. of mercury lowers the temperature to – 200deg. C. The gas then passes into a regenerator coil, which is enclosed in a vacuum vessel, and expanding at a valve passes upwards through the interstices of the coil and the annular space surrounding the chambers through which the gas first passes to an outlet whence it can return to the main supply pipe. The liquid which separates from the gas is ultimately collected in a vacuum vessel. The apparatus, with the exception of the compressor, motor, and Hampson's air liquefier, is comparatively inexpensive. About £50 is required for the additional apparatus, and each time liquid hydrogen is made involves a further expenditure of about a sovereign.

Dr. Hampson said he would like to offer a correction. Dr. Travers had said that he (Dr. Hampson) was the first to liquefy air by the application of the counter current process to the Joule-Thomson effect. Although he was the first to make the proposal, he was not the first to apply it. He made the proposal to Prof. Dewar's assistant in 1894, and air was liquefied by Prof. Dewar by this method. Dr. Travers had referred at length to a valve which he (Dr. Hampson) had devised, but as it was straightforward common-sense, he did not wish to accept any credit for the use it had been to the author in his experiments. He would like to call attention to the remarkable features of the work in two respects—the economy of means and the magnitude of results. By means of liquid hydrogen Prof. Ramsay and Dr. Travers had succeeded in obtaining the physical and other properties of some of the rarer gases.

Prof. S. P. Thompson said the author had asserted that the Joule-Thomson effect for hydrogen changes in sign at some temperature, and expressed his interest in the fact that it was possible to get a cooling effect by allowing hydrogen to expand.

Mr. Boys asked if it was necessary or desirable to allow the hydrogen to expand to atmospheric pressure.

Dr. Travers said the mechanical advantages of this were great.

Dr. Lehfeldt asked if there had been any attempt to determine the temperature of the liquid, and, secondly, if the apparatus could be employed to determine the magnitude of the Joule-Thomson effect.

Dr. Herker asked if the temperature at which the Joule-Thomson effect changes sign was known.

Dr. Donnan said that the effect changed sign at the temperature at which "P V" was a minimum.

Dr. Travers, in reply to Dr. Lehfeldt, said he had not determined the temperature of the liquid, and the apparatus was not suitable for measuring the Joule-Thomson effect. He should say that the change of sign occurred about –150deg. C. It was Daniell Berthelot who first pointed out that the change of sign corresponded with the minimum value of "P V," but the experiments of Amagat on the relation between pressure and volume were not sufficiently accurate to fix the temperature.

A paper on "**The Anomalous Dispersion of Carbon**," by **Prof. R. W. Wood**, was taken as read. Experiments were made with smoke films and with films deposited on plate glass in a vacuum by an incandescent lamp. The dispersion was first measured with a Michelson interferometer, illuminated with monochromatic light of various colours obtained by prismatic analysis. The fringes were photographed and measured, readings being obtained between wave lengths ·000040cm. and ·000066cm. The results show a steady increase of refractive index from blue to red. The refractive index for sodium light was measured by estimating the thickness of the film and the fringe displacement, and was found to be 2·2. A prismatic deposit of smoke was then made by allowing a piece of plate glass to move uniformly backwards and forwards over the top of a small flame. The deviation produced by this prism was measured by means of a direct vision spectroscope, with the prisms removed. Experiments were performed with red and blue light. The mean deviation of red and blue was taken for sodium light, and this result was in good agreement with the deviation obtained by the interferometer method.

A paper on "**The Refraction of Sound by Wind**," by **Dr. E. H. Barton**, was taken as read. Assuming that the wind is everywhere horizontal, and does not vary in any one horizontal plane, but is different at different levels, then the following results are obtained for rays in the same vertical plane as the wind: (1) the direction of propagation is not usually at right angles to the wave-front, where there is a wind, consequently the cosecant law for the wave-front needs supplementing by another expression giving the direction of the ray; (2) total reflection cannot occur if the wave-front is initially horizontal; (3) in a region where the horizontal wind increases uniformly as we ascend, the rays instead of forming a catenary describe a more complicated curve, which, however, reduces to a parabola in the special case of rays whose wave-fronts are horizontal. In the paper the relation between direction of propagation and wave-front is first worked out, and then the refraction of waves and rays on crossing into a new wind zone is considered. This principle is then applied to the diffraction through any number of parallel wind zones, and it is shown that the final inclinations of wave-fronts and rays are independent of the characteristic constants of the intermediate zones. It is shown that since a cosecant cannot have a value between +1 and –1, total reflection becomes possible. If, however, the wave-front is initially horizontal there is no refraction of the wave-front and no total reflection, but the ray deviates without limit from the vertical and tends to correspond with the wave-front. When reflection occurs it follows the ordinary optical law.

The society then adjourned until Dec. 14, when the meeting will be held at the Royal College of Science, South Kensington.

LEGAL INTELLIGENCE.

THE BRITISH ELECTRIC TRACTION COMPANY, LIMITED, AND THE COMMISSIONERS OF INLAND REVENUE.

Judgment was given in this case on Wednesday in the Queen's Bench Division. The questions involved the rights to use certain tramway lines, and that rent should be paid for same. There was an agreement to the effect that £900 a year was to be paid for the repairs to the tramway line, to be undertaken by the Corporation; a further agreement to pay another sum as indefinite rent; and, still further, one to take all the electrical energy from the Corporation working the tramways, and to pay for it at least a minimum of £4,000 a year. It was argued that the £900 a year for repairs was rent, and chargeable as rent; that the £4,000 a year was a bond or covenant, also chargeable. The questions submitted by the Commissioners of Inland Revenue for the Court were whether the instrument was chargeable with the several sums of £20. 15s., 10s., and £105, and, if not, with what duty the instrument was chargeable. Section 77 (2) of the Stamp Act, 1891, enacts as follows: "No lease made for any consideration or considerations in respect whereof it is chargeable

Digitized by Google

with *ad valorem* duty, and in further consideration either of a covenant by the lessee to make, or of his having previously made, any substantial improvement of or addition to the property demised to him, or of any covenant relating to the matter of the lease, is to be charged with any duty in respect of such further consideration."

Mr. Justice Phillimore held that the £900 was rent, and that the £4,000 a year was a part of the consideration for the lease, and as such chargeable *ad. val.* accordingly.

Mr. Justice Kennedy dissented, and held that neither sum was rent, and would therefore be relieved from duty under Section 77, Sub-Section 2—that is to say, that when a lease is made in respect of a consideration it was chargeable, and shall not be chargeable in respect of subsidiary subjects.

Mr. Justice Phillimore withdrew his judgment; therefore the judgment of Mr. Justice Kennedy prevailed, and the duty chargeable on the instrument was accordingly reduced to £16. 5s., together with the 10s. in respect of Clause 5, the liability for which was not disputed.

FIXING UP A TELEPHONE.

Mr. H. E. Childs, Liverpool road, Islington, on Nov. 22 obtained judgment against Messrs. Charles Atkins and Nisbet, 1, Waterlane, for £3. 3s., for fixing up a telephone at their premises. The defendants paid £2. 10s. into court, and said they thought that was more than the plaintiff was entitled to. At the first hearing of the case it was contended that an incompetent workman was sent in the first place, and that the work might have been done by an ordinary bellhanger. The case was now undefended.

WOLVERHAMPTON CORPORATION v. BRITISH ELECTRIC TRACTION COMPANY, LIMITED.

On Thursday last **Mr. Justice Joyce** delivered judgment in the above case, which was reported in our issue of Nov. 23. He found for the Corporation of Wolverhampton on all points at issue, and gave judgment accordingly, with costs The defendants have not yet decided whether they will appeal against the judgment.

COMPANIES' MEETINGS AND REPORTS.

BRITISH WESTINGHOUSE ELECTRIC AND MANUFACTURING.

In the first annual report, for the period from July 10, 1899, to July 31, 1900, the directors state that in addition to the orders and contracts taken over from the vendors, amounting to £279,000, orders have been received and contracts have been entered into since the incorporation of the Company amounting to £550,000, thus bearing out the expectation expressed in the prospectus as to the development of the business. The net profit for the period under review, exclusive of the amount guaranteed by the vendors, is £10,777. 7s. 7d., after providing for expenses of management, directors' fees, and all other charges, which is considered satisfactory, considering that the works at Trafford Park are still in course of construction. Out of this profit, supplemented by the guarantee, the directors distributed an interim dividend on the 6 per cent. preference shares in May last, amounting to £7,551. 2s., calculated on the amounts paid up to Jan. 31, and now recommend the payment of a final dividend for the six months ending July 31, ammounting to £15,000, making 6 per cent. thereon for the whole period. The directors are pleased to report that the works at Trafford Park, Manchester, are making good progress, the agreement for the purchase of the land having been concluded, the plans for the entire works having been prepared by Mr. Thomas Rodd, of Pittsburg, U.S.A., from information and drawings supplied by the American Westinghouse Electric and Manufacturing Company under their agreement, and the principal contracts for the construction work having been placed. The requisite connections between the works and the principal railways have also been completed. In view of the large staff which will necessarily be required in connection with the works, a number of young English engineers have been sent to serve an apprenticeship in the works of the American company at Pittsburg. By this method of forming the staff, the directors believe that the principles of manufacture which have been so successfully worked out in the United States will be reproduced in the works at Manchester. Arrangements are being made to provide suitable dwellings for the operatives to be employed in the works, in which the men and their families will be well housed at reasonable rates with great advantage to the Company. Technical and commercial managers have also been appointed, and are making themselves familiar with the approved methods adopted at the works at Pittsburg, which, as is well known, are equipped with the most modern plant and appliances, and where about 7,000 men are employed. The directors intend to establish branch offices in the more important manufacturing centres, and they have recently opened an office in Manchester, at Haworth-buildings, 5, Cross-street. In July this Company took part in the Electric Traction Exhibition at the Agricultural Hall, Islington, and at the close of the exhibition the car and track shown by the Company were purchased by the London County Council for their experimental work at Camberwell. Pursuant to the provisions of the special resolution passed and confirmed in August, 1899, empowering the directors to appoint any qualified person an additional director the Board have to report that they have appointed Mr. Lukach and Mr. Kobbé to be directors of the Company. The appointments do not require confirmation by this meeting. Under the articles of association no directors retire from office at this meeting. The Board appointed Messrs. Deloitte, Dever, Griffiths, and Co. the first auditors of the Company, and they will be proposed for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Kendal.—The Corporation invite tenders for the supply and erection of various plant. Tenders by Dec. 1. Details in our advertisement columns.

Blackpool.—The Corporation invite tenders for the supply of arc lamp carbons and oils for one year. Tenders by Dec. 17. Details in our advertisement columns.

Brighton.—The Council invite tenders for the construction of the permanent way of the tramroads. Tenders by Dec. 13. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for supply of 12 workmen's tramcar bodies. Tenders by Dec. 1. Details in our advertisement columns.

Partick.—The Commissioners invite tenders for electricity meters, demand indicators, and fuses. Tenders by Dec. 4. Details in our advertisement columns.

Aberdeen.—The Electric Lighting Committee invite tenders for the supply and erection of storage batteries. Tenders by Dec. 22. Details in our advertisement columns.

Birkenhead.—The Corporation invite tenders for switchboard and instruments for Craven-street generating station. Tenders by Dec. 4. Details in our advertising columns.

Leigh.—The Electricity and Tramways Committee invite tenders for the supply and erection of electricity mains. Tenders by Dec. 17. Details in our advertisement columns.

Bermondsey.—The Vestry invite tenders for arc lamp columns, arc and incandescent lamps, automatic switches, and fittings. Tenders by Dec. 3. Details in our advertisement columns.

Mendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Swindon.—The Corporation invite tenders for three high-speed triple-expansion steam dynamos, one balancer, and one motor-generator. Tenders by Dec. 24. Details in our advertisement columns.

Harrogate.—The Corporation invite tenders for two high-pressure 30ft. by 8ft. 6in. Lancashire boilers, with fittings complete, and economiser. Tenders by Dec 25. Details in our advertisement columns.

Bristol.—The Electrical Committee invite tenders for induced-draught plant, steam and electric feed and general service pumps, and water-softening plant. Tenders by Dec. 20. Details in our advertisement columns.

Battersea.—The Council invite tenders for the supply of ordinary and prepayment electricity meters, in accordance with specification No. 10. Tenders by Feb. 1, 1901. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the overhead electrical equipment of tramways in the borough of Portsmouth, and extending to Cosham, Hants. Tenders by Dec. 7. Details in our advertisement columns.

Blackburn.—The Highways Committee invite tenders for the electric wiring of the underground conveniences in Church-street, Blackburn. Plans, etc., may be seen at the Borough Engineer's Office. Tenders by Dec. 6.

Leigh.—The Electricity and Tramways Committee invite tenders from manufacturers for the supply of 1,000 220-volt incandescent lamps during a period of 12 months. Tenders by Dec. 17. Details in our advertisement columns.

Ilford.—The School Board invite tenders for wiring and all ordinary fittings for about 200 lamps at 16 c.p., the Higher-Grade School, Melbourne-road, Ilford, Essex. Tenders by Dec. 17. Details in our advertisement columns.

Rathmines.—The Electric Lighting Committee invite tenders for the supply and erection of various plant for the extension of the municipal electricity works. Tenders by Jan. 10, 1901. Details in our advertisement columns.

Glasgow.—The Caledonian Railway Company invite tenders for telegraph and electrical appliances. Specifications, etc., may be obtained from Mr. J. Lorimer, stores superintendent, Charles-street, St. Rollox, Glasgow. Tenders by Dec. 17.

Sunderland.—The Corporation invite tenders for the whole of the work necessary in erection of buildings for new electric light station, Hylton-road. Particulars, etc., may be obtained at the

Digitized by Google

Borough Electrical and Tramway's Engineer's Office, Dunning-street. Tenders by Dec. 10.

Bexhill.—The Council invite tenders for the supply, delivery, and erection of a water-tube boiler and pipework and one 150-kw. steam dynamo at their electricity supply station. Tenders by Dec. 10. Details in our advertisement columns.

Southwark.—The Electric Light Committee invite tenders for the supply and erection of certain back E.M.F. cells at the Corporation electric light station, Penrose-street, Walworth-road. Tenders by Dec. 3. Details in our advertisement columns.

St. Pancras.—The Guardians of the Poor invite tenders for the installation of the Cook's-terrace Infirmary, Pancras-road, N.W., with electric light, according to drawings and specification. Tenders by Dec. 20. Details in our advertisement columns.

Oldham.—The Tramways Committee invite tenders for the erection of a tramway car depot at Wallshaw, within the borough. Specifications, etc., may be obtained from Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Town Hall, Oldham. Tenders by Dec. 5.

Leigh.—The Electricity and Tramways Committee invite tenders for the supply and delivery of the following motors and starting switches: one 10-h.p. motor, four 3-h.p. motors, three 2-h.p. motors, and three 1-h.p. motors. Tenders by Dec. 17. Details in our advertisement columns.

Tooting.—The Metropolitan Asylums Board invite tenders for the execution of certain wiring and other works in connection with the proposed electric light installation at the asylum now in course of erection at Tooting Bec. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Brighton.—The Council invite tenders for the supply and delivery of the following: points, crossings, etc., soleplates, manhole covers with frames, gully grates with frames, tie-bars, fish-bolts, and other bolts for fastenings, etc. Tenders by Dec. 6. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the permanent-way construction and underground feeders in connection with the equipment for electric traction of the tramways in the borough of Portsmouth, and extending to Cosham, Hants. Tenders by Dec. 7. Details in our advertisement columns.

Wolverhampton.—The Tramways Committee invite tenders for steel stanchions, wrought-iron roof trusses, rolled-steel joists, etc., and other works required at the tramway car depôt. Plans, etc., may be seen on application to Mr. J. W. Bradley, borough engineer and surveyor, Town Hall, Wolverhampton. Tenders by Dec. 3.

Oldham.—The Tramways Committee invite tenders for the supply and erection of the iron and steel work required in the completion of a car depot at Wallshaw, within the borough. Specification, etc., may be obtained from Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Town Hall, Oldham. Tenders by Dec. 5.

Bristol.—Tenders are invited for the installation of the electric light at the Bristol General Hospital, Bristol. Specification, etc., may be obtained from the secretary, Mr. W. Thwaites, Bristol General Hospital, on payment of a deposit of £2. 2s., which will be returned on receipt of a bona fide tender. Tenders by 11 a.m. on Dec. 3.

Ayr.—The Tramways Committee invite tenders for Section 2, overhead work: Part 1, poles, centre and side brackets, section boxes, etc.; Part 2, complete overhead electrical equipment; Section 3—underground work: supply of feeders, distributors, telephone cables, conduits, trenching, etc. Tenders by Dec. 7. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for the supply of materials and erection and completion of proposed alterations and additions to the buildings in connection with the meter-testing and stores departments at the electricity works, Bolton-road, Bradford. Specifications, etc., may be obtained from Mr. R. A. Chattock, M.I.E.E., city electrical engineer, Town Hall, Bradford. Tenders by Dec. 6.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS.

London.—The London School Board has been recommended to accept the tender of Mr. J. C. Christie, at £445, for wiring, etc., for electric lighting at St. John's-road School.

Sunderland.—The Town Council have accepted the contract of Messrs. Dick, Kerr, and Co., Limited, for 24 motorcars of the top-seat type, together with track cleaner and traverser, at £675 per car. All of these cars will be equipped with standard air brakes.

London County Council.—The Council have accepted the tender of the Gilbert Arc Lamp Company, at £2,515, with certain modifications of the specification, which are mentioned in another column, for the lighting of Victoria-embankment and Westminster Bridge.

Greenwich.—The Guardians have accepted the tender of Messrs. Cooksley, of Lightcliffe, Yorkshire, at £4,338, for the electric lighting of the new workhouse at Grove Park. The highest tender was £9,907.

Aberdeen.—The Town Council have accepted the tender of J. Leith, jun., 3, Cattofield-place, Aberdeen, at £9,904. 15s., for the supply of materials and the construction of works in connection with the laying down of the permanent way of new electric tramways.

Ayr.—The Town Council have accepted the tender of Messrs. Siemens, at £2,505, for a 200-kw. complete set for a voltage of 500 to 550, the delivery to be not later than 9½ months from date. It is conditioned that Messrs. Siemens in February, 1901, take out and dismantle at their own expense the present No. 3 plant, substituting for it the above 200-kw. set, at the difference of cost, they allowing £2,070, less 5 per cent. per annum for the use of No. 3 set.

Devonport.—The following tenders have been recommended for acceptance:

A. N. Coles, Plymouth, buildings (exclusive of chimney and flues)	£5,433
S. Z. de Ferranti, Limited, Hollinwood, two vertical engines	3,200
Electric Construction Company, Wolverhampton, two 300-kw. generators, balancer, battery, booster, and motor	3,659
Electric Construction Company, switchboard, lighting and traction (subject to certain deductions)	2,922
Ashmore, Benson, Pease, and Co., Stockton-on-Tees, storage battery	2,600
Higginbottom and Mannock, Manchester, 10-ton travelling crane	326
Babcock and Wilcox, two boilers (with mountings complete)	1,950
Bennis and Co., stokers and automatic steam damper	535
Green and Son, economiser	440
Glenfield and Kennedy, tanks and meter	274
Mather and Platt, oil filter	70
Carruthers and Co., valve chest	60

London, E.—The Whitechapel District Board of Works have received the following tenders for the erection of a chimney shaft and the construction of economiser chambers, flues, and cableways at the new electrical supply station yard, Osborn-street, Whitechapel, E.

Chimney shaft only.

R. Anderson and Co., 101, Leadenhall-street, E.C.	£8,475
Gibb and Co., 1A, Birchfield-street, West India Dock-road, Limehouse, E.	8,834
Watts, Johnson, and Co., 785, Commercial-road, Limehouse, E.	9,775
F. Minter, Ferry Works, Page-street, Westminster, S.W.	7,916
W. Neil and Co., 165, Turner's-road, Burdett road, Bow, E	9,322
B. E. Nightingale, Albert Works, Albert-embankment, Lambeth, S.E.	7,763
T. Smart, Trent Bridge, Nottingham	8,021
Harris and Wardrop, 10, Wallwood-street, Limehouse, E.	9,686
Myles and Warner, 20, Sett-street, Stalybridge	7,157
Wilson Bros., 31, Berens-road, Kensal Rise, N.W.	6,189

Flues, cableways, &c.

R. Anderson and Co.	6,475
Gibb and Co.	5,516
Watts, Johnson, and Co.	4,911
F. Minter	5,112
W. Neil and Co.	5,619
B. E. Nightingale	4,860
T. Smart	5,143
Harris and Wardrop	5,523
Myles and Warner	5,851
Wilson Bros.	4,999

BUSINESS NOTES.

TRACTION.

Ilford.—It is rumoured that the G.E.R. Company contemplate running an underground railway to Ilford or beyond.

Personal.—Mr. A. R. Bramley, for the past six years manager and secretary of the Bradford and Shelf Tramway Company, has been appointed manager of the Birkenhead electric tramways.

Accident - A collision between a tramcar and a dray laden with wool occurred in Gibbet-street, Halifax on Saturday noon owing to the fog, but was, happily, unattended with injury to any person.

Surbiton.—The proposals of the London United Tramways Company and the Kingston Corporation to construct tramways in the Council's area has now been agreed to by the Rural District Council.

Walsall.—A special meeting of the Urban District Council is to be held, at which representatives of the electric tramways company are to be present to give the Council full particulars of their scheme.

Gosport.—The Gosport and Alverstoke Urban District Council on Tuesday definitely decided to give the promoters of the Gosport Tramway Company notice of the Council's intention to purchase the tramways.

Digitized by Google

Folkestone.—The owners and ratepayers, by their poll on Tuesday, reversed the decision to authorise the Corporation to proceed for a Bill to incur an expenditure of £100,000 upon municipal tramways.

Gateshead.—Rapid progress is being made with the laying of the tramlines at Gateshead. A start has just been made with the work in Half Moon-lane, and it is stated that for a time traffic will have to be diverted.

China War.—The Chinese have destroyed railway and telegraph lines in Manchuria, or a distance of 300 versts. The total damage is estimated at 10 million roubles. The repairs of the line will probably cost 150,000 roubles.

Kingston.—The long-expected meeting of ratepayers, which was held last week, had a curious result. First, the Corporation Bill was rejected, then it was decided to oppose the London United Tramways Bill, and, thirdly, a poll was demanded on the first resolution.

Italy.—The Government are preparing a scheme for the introduction of an electric railway able to do the journey from Rome to Naples in three hours instead of five, as at present. The system adopted will probably be overhead traction, and the motive force will be supplied from the rivers in the district.

Cleator Moor.—The Urban District Council have been notified that application is intended to be made to Parliament in the ensuing session for an Act to authorise the laying down of electric tramways and tramroads in West Cumberland including some streets and roads within the district of the Council.

Dundee.—A deputation from the Aberdeen Corporation visited Dundee on Monday to inspect the electric tramway system, carshed, and the workshops at the electric station. The visitors appeared to be specially interested in the lifeguards on the cars, and also in the fitting up and general arrangement of the workshops.

Birmingham.—The work of reorganising the Bristol-road service is proceeding satisfactorily. The poles which are to carry the overhead wires are nearly all in position. A contract for 20 new cars has been placed, and it is hoped that the whole work will be completed by March next. The proposed Bill provides for three extensions.

Leamington.—The British Electric Traction Company have concluded an agreement with the shareholders of the Leamington and Warwick Tramways and Omnibus Company, Limited, for the purchase of their undertaking, and they have obtained the consent of the Corporations of Leamington and Warwick to the installation of an overhead system of electric traction.

Lake District.—It is now stated that, contrary to former announcements, the British Electric Traction Company will not again introduce their scheme for a light railway between Windermere and Ambleside this year. Another application will be made to the Light Railway Commissioners when a scheme more satisfactory to those concerned has been drawn up.

Surrey.—The Corporation of Kingston-upon-Thames have on more than one occasion pressed for an expression of the views of the County Council with respect to the Corporation's intended tramway scheme, and the Parliamentary Committee have directed a reply to be sent intimating that until they are in possession of the details of the various schemes affecting the district, they are unable to make any recommendation to the Council on the subject.

Blackpool.—A start has been made with the extension of the Blackpool trams round Marton, and the work is expected to be finished by Whitsuntide. The proposed amalgamation with St. Annes having been abandoned, the proposal to construct a tramway there has been withdrawn from the Bill about to be proceeded with by the Corporation, though powers are being sought to lay tramways in several other parts of Blackpool, and to double the Lytham-road tramways.

Maryport.—The General Purposes Committee have been authorised in connection with the proposed formation of a company to construct a tramway extending from Cleator Moor, through Whitehaven, Workington, to Maryport, Allonby, and Silloth, to take the necessary steps to safeguard the interests of the Council, to obtain legal advice if required, to confer with the neighbouring local authorities interested, and, if deemed necessary, to agree with any joint action with the other authorities.

Paris.—The Paris Metropolitan Railway Company, having commenced the construction of a second section of its conceded lines, is about to raise its share capital from 25 million francs to 50 millions by the issue of 100,000 new shares of 250fr., reserved for holders of the 100,000 shares now in circulation. As before, the tunnelling and permanent way will be executed by the city of Paris, the company building the stations, providing the rolling-stock, working the lines, and sharing the receipts in equal parts with the municipality.—*Economist.*

Leeds.—As preliminary steps towards equipping the Burley and Cardigan-road tramway route with electric traction, arrangements have been made for breaking up the ground and laying down feeder wires from the Calls to Headingley by way of Swinegate, City-square, Quebec-street, St. Paul's-street, Park-lane, Burley-road, and Cardigan-road. Victoria-road will be similarly treated. The work of erecting poles for carrying the overhead electric wires between North-street and Meanwood-road and Woodhouse-street commenced on Wednesday last week.

Sixty Pounds a Foot.—An enquiry was opened at the Surveyors' Institution last week to fix the amount of compensation to be paid by the City and South London Railway Company to the wardens of the church of St. Mary Woolnoth. The crypt and land in the vicinity of the church, which was taken on the present valuation, was worth £260,700, and with the cost of reinterring the bodies buried in the crypt and sundry other items and expenses, the claim amounted to £291,606. After hearing expert evidence on behalf of the churchwardens, the case was adjourned.

London United Tramways.—The machinery at the central power station of the London United Tramways Company at Chiswick has been started. No. 1 engine, of 1,000 h.p., was started last week. During the present week a second engine of similar capacity will be started, and the third engine will be ready in about a fortnight, which completes the installation for the operation of the 16 miles of tramway route from Shepherd's Bush to Acton, from Shepherd's Bush to Chiswick, *vid* Goldhawk-road, and from Hammersmith-broadway to Kew, Brentford, and Hounslow.

Hendon.—A Bill is to be introduced into Parliament asking for powers to extend the underground electric railway from Hampstead to a point not far from the Guards' Convalescent Home at Golder's Green. There the line will emerge from the ground and convey the passenger by means of a number of cars carrying their own motors to Central Hendon and along Regent's Park-road to Finchley. The Middlesex County Council, it will be remembered, have already secured powers from the Light Railway Commissioners to lay certain lines in the districts of Hendon and Finchley.

Bournemouth.—Sir George Merrick, owner of the East Cliff frontage at Bournemouth, has offered the Corporation a long lease of the overcliff between Bournemouth and Boscombe at a small ground rent. He retains, according to the *Daily Chronicle*, his rights in the cliff front and the foreshore, but the offer, if accepted, will allow the town the privilege of a magnificent top cliff drive of considerably over a mile in length. Sir George does not announce the abandonment of the undercliff drive scheme, and hints in his letter at an electric tramway in the future and some building developments near Boscombe and Bournemouth piers.

Rochdale.—At the last meeting of the Tramways Committee a proposition was agreed to expressing the willingness of the committee to enter into negotiations with the Middleton Light Railways Company in regard to the Corporation extending their lines to the centre of Castleton. Prior to the incorporation of the district in the borough the company obtained powers under which they can construct tramways from Middleton to Sudden. Mr. S. S. Platt, the borough surveyor, was appointed permanent-way engineer; and it was decided to ask Mr. T. A. Lacey, of London, to meet the committee with a view to his appointment as electrical engineer in connection with the tramway scheme.

Paisley.—At a recent meeting of the Town Council, it was moved that the minute recommending the Council to apply for a provisional order for the construction of a tramway line in the east end of the town be not approved of. It was said that this was simply an effort to get in the thin edge of the municipalisation wedge, and it was not fair to the ratepayers, who had by a large majority voted against the Corporation working the tramways. On the other hand, it was agreed that it was essential that Paisley should be put in the position of having a tramway connection with Glasgow, and they asked powers for that purpose, and finally the approval of the minutes was carried by a large majority.

Tunbridge Wells.—The borough electrical engineer has prepared a report on the advisability of the establishment of an electric tram service in the town. Mr. Boot makes recommendations as to the route, and estimates the cost of construction at £33,000. From returns taken from all over the kingdom, about 6d. per car mile, and in most cases less, covered the total working expenses. However, in Tunbridge Wells he took 8d. per mile, on account of the hills. The number of car miles estimated to be run in 313 days, working 10 hours per day, with four cars on the route, was 75,120. The cost per annum equalled £2,504; interest and sinking fund on the capital expenditure at 6 per cent. equalled £1 980—making a total of £4,484 per annum. Referring to other returns in the kingdom, and allowing a very modest return indeed compared with them, each car should earn £10 per day, or producing a total revenue of £12,250 per annum, and leaving a profit, after paying 6 per cent. on the capital, of £8,036.

New Issue.—The Brisbane Electric Tramways Investment Company, Limited, are making an issue of £400,000 4½ per cent. first debenture stock at par (part of a total authorised issue of £500,000). The concession for the Brisbane tramways is now, and will continue to be, vested in the Brisbane Tramways Company, Limited, all the shares of which company—viz., 150,000 fully paid shares of £5 each (except 107 of such shares held by its directors and first subscribers)—will belong to this company, and will be transferred to the trustees, and constitute the security for the first debenture stock of this company. The Brisbane Tramways Company, Limited, will be free of all mortgages and debentures whatever. The shares thus held—viz., 149,893 shares of £5 each—will carry dividends in respect of profits from June 30, 1900. The proceeds of the present issue will be applied in paying off the existing debentures and other debts and liabilities of the Brisbane Tramways Company, Limited, and in the construction and equipment of the extensions now proposed to be carried out. The present length of the Brisbane Tramways Company's lines is upwards of 33 miles of single lines of tramways, and the extensions now contemplated will represent upwards of 12½ miles of additional single lines of tramways. The revenue account of the Brisbane Tramways Company, Limited, for the six months ended

Digitized by Google

June 30, 1900, showed net profits at a rate which, after payment of all outgoings, should give a net profit to this company of upwards of £36,000 per annum.

Manchester.—Mr. C. H. Wordingham has prepared a report to the Electricity Committee, in which he deals with some of the statements in the report of the general manager of the Tramways Committee, which was recently presented to the Tramways Committee, with regard to the supply of electrical energy for the working of the tramways. As regards the generating station in Stuart-street, Bradford, Mr. Wordingham says (according to the *Manchester Guardian*) that, although the Electricity Committee arranged for the purchase of the land in December, 1897, the purchase was not completed until October, 1898. There was then a further delay of six months on account of the Tramways Committee having under consideration the question whether it would not be better themselves to provide the electrical energy for driving the trams. He also states that details and plans were asked for from them, with an account of the dates when electrical energy would be required, and a definite order; but these have not been forthcoming. He replies to the statement that the Tramways Committee are pushing forward rapidly with the preparations for the taking over of the line by instalments, and also that the permanent way is being rapidly reconstructed, and says that, as a matter of fact, the tramways department themselves are hopelessly behindhand with this work. He describes the arrangements for the supply of energy to the different parts of the city, and says that his report of Oct. 23 clearly shows that the Electricity Committee will be prepared to furnish the energy for the first three tramway routes long before these routes are ready to take the supply. He deals with other work done by his department, and in conclusion says: "I have to say that I consider that the report of the general manager is so drawn as to leave the impression that the Tramways Committee will be quite ready with their lines so as to take current on the date named in their communication to the Electricity Committee of July 22, 1899, and that they will be prevented from opening the lines on the dates named in that communication on account of the Electricity Committee not being in a position to supply them with the necessary electrical energy. In point of fact, the Tramways Committee are already five months' late with the first section, and have not begun the work of reconstruction of any one of the three remaining sections, while the Electricity Committee will be ready to supply the electrical energy to the first section some time before the Tramways Committee can be ready. What has happened in regard to the first section of lines may be expected to happen with the remainder, and it is by no means evident at the present time that the Electricity Committee will be greatly behind the Tramways Committee. Both committees are engaged on very large and difficult schemes, and it will not be surprising if both find themselves in the position of having underestimated the time required to carry them out."

LIGHTING AND GENERAL.

Grimsby.—The telephone question has been adjourned till next week.

Ayr.—Mr. Hammond's resignation as consulting engineer has been accepted.

Ashton.—The Guardians have resolved to instal the electric light at the union offices.

Frome.—The Urban District Council have decided to apply for an electric lighting provisional order.

Newark.—The Sanitary Authority have decided to proceed with a scheme for providing the electric light.

Dunstable.—The Town Council have agreed to apply for a provisional order to supply electric light in the town and district.

The New Cable.—It appears that owing to the unfavourable weather usually prevailing at this time of the year, the new Anglo German telegraph cable cannot be laid before the spring.

Cheshunt.—The Council intend to apply for an electric lighting provisional order, and have appointed an Electric Emergency Committee, comprising Messrs. Cull, Greenleaf, Robinson, and Shackle.

Battersea.—Application is to be made to the London County Council for the advance of £20,000 further on account of the general electric lighting scheme, sanction for which has been obtained.

Eastbourne.—We learn that Mr. A. J. Bessant, of Grove-road, Eastbourne, has been commissioned to effect installations of the electric light in St. Anne's Church, Eastbourne, and the County Hall, Lewes.

London Gazette.—The last day for receiving proofs in the estate of G. H. Bentley, 63, Cross-lane, Earlestown, Lancashire, is Dec. 11. Mr. G. F. Clarke, 71, Cross-lane, Earlestown, Lancashire, is trustee.

Dublin.—Mr. P. C. Cowan has held an enquiry in the city hall into the application of the County Borough Council for sanction to a supplemental loan of £10,400 for electric lighting.

City and South London Railway Co.—This Company has recently issued 10,000 shares, of the nominal value of £10 each, at the price of £5. 10s. per share. The shares were offered to the share and debenture holders only.

Inverness.—A modified proposal which has now been made *re* the proposal for transfer of the Corporation's provisional order to the North of Scotland Electric Light and Power Company is before a committee of the Town Council.

Islington.—The Electric Lighting Committee are making enquiries regarding the discharge of coal breeze and dust from the electric lighting shafts to the great annoyance and serious loss of the inhabitants of Eden-grove.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to General Electric (1900), Limited, 5 per cent. cumulative preference shares of £1 each, and £150,000 4 per cent. first mortgage debenture stock.

Eastern Extension Telegraph Co.—At an extraordinary meeting of the Eastern Extension, Australasia, and China Telegraph Company last week, at Winchester House, Sir J. Wolfe Barry presiding, the special resolution passed on Nov. 7, referring to remuneration of directors, was confirmed.

Ashton-under-Lyne.—Mr. N. Appelbee, the engineer of the Cardiff Corporation electric lighting works, has been appointed as electrical engineer of the Corporation. There were 47 applicants for the post. The Corporation do their own lighting and supply the current for the tramways on the combined system.

Edinburgh.—At the meeting of the Electric Lighting Committee on Wednesday it was resolved to recommend that application should be made for consent to borrow a further sum of £76 000 for the execution of capital works. This sum will make a total of £700 000 for which borrowing powers have been authorised by the Secretary of Scotland in connection with the electric lighting undertaking.

Appointments Vacant.—The Doncaster Corporation have vacancies for two pupils at their electricity works for a period of three years.—The Electric Light Committee of Battersea invite applications for the appointment of engineer, at a salary of £350 per annum, with residence at the central station when the works are completed. Particulars of these vacancies appear in our advertisement columns.

Wind Power.—An electric lighting installation has recently been laid down at Boyle Hall, West Ardsley, in which wind is the only motive power employed for generating the currents. There are 50 sails, set radially in a circular frame about 30ft. in diameter. A large pulley fixed on a horizontal shaft in an adjacent building drives the dynamo. The duty of this machine is to charge the storage cells, which are sufficiently large to run the 109 lights for about eight days in winter should there be no wind for that length of time, and more than a fortnight in summer.

Willesden.—At a meeting of the District Council on Tuesday, it was reported that the engineer had received the bills of quantities in connection with the main and sub-electricity stations. The Council decided to apply to the Local Government Board for sanction to a loan of £52,550, for use as follows: buildings, walls, sites, works, chimney shafts (main station), £36,104; tenants' compensation, £121; cost of road, £325; coal sidings, £2,500; offices and sub station, £13,500. It was pointed out that the surveyor's estimate was within £1,500 of the total amount.

Manchester.—The local papers are publishing conflicting reports as to the appointment of a tramway expert to supervise conversion of their tramways for electric driving. Thus, on the 28th inst., in the *Manchester Guardian* it was reported that Mr. H. F. Parshall, the well known expert, had been appointed, and in yesterday's issue of the same paper it is stated that the committee still have the matter under consideration. It is a great pity that the committees in Manchester do not keep these informal notices of their meetings out of the Press. As a rule the proceedings of all committees should be kept private, and their recommendations to the Council alone made public.

Charing Cross and City Station.—We are informed by Messrs. H. M. Salmony and Co., Limited, of 118 and 120, Charing Cross-road, London, W.C., British representatives of E.A.G., late W. Lahmeyer and Co., of Frankfort-on-Main, that a contract for generators and motor dynamos for the Charing Cross and City station has been given to Messrs. Lahmeyer. The switchboard will be provided with Messrs. Lahmeyer's patent switching gears, which are arranged in such a manner that no high-tension current is on the main board itself. By this arrangement, the greatest safety to human life is ensured. Even the instruments recording the high-tension current are connected in such a way that they can be handled with perfect safety, as no high tension current reaches them.

Kensington.—At the last meeting of the Guardians a report came up from the Special Electric Lighting Committee. They were unanimously of opinion that it was desirable to light the workhouse infirmary, and office buildings in Marloes-road by electricity, and the only question was whether the electricity should be obtained from a public company or be generated by the Guardians' own plant on their own premises. After consideration of the relative merits and costs of both systems, and lengthy consultation with Prof Robinson and ascertaining that the future cost of obtaining the supply from a company would be about £1 040 a year, as against a future cost of £650 a year—after 20 years—if the Guardians generated their own supply, the committee have come to the conclusion that it would be more satisfactory, and in the long run more economical, for the Guardians to undertake the work of generating. This report was adopted, and the Board decided to instruct Prof. Robinson to prepare and submit a complete plan and specification for the buildings, machinery, and plant required, at an estimated cost of £12,500. It was mentioned that the cost of the gas at present was £1,400 a year for lighting, and that the electric light for the first 20 years was estimated to cost £1,470 a year. The great saving, however, would be found after 20 years, as shown above.

Digitized by Google

Shildon.—The draft agreement with the Northern Counties Electric Supply Company for the lighting of the Shildons has been sealed.

Dover.—Amongst the applications for private Bills will be found one of the Corporation, seeking powers to purchase the undertaking of the electricity supply company.

Dredgers.—We learn that there are about 90 dredgers for mining operations being built for various parts of New Zealand, and that the demand there is so active that the supply is unable to cope with it. Electricity is to be the motive power.

Leeds.—The Highways Committee have granted an application of the Corporation Electric Lighting Committee to open out 14 streets at Beeston, Hunslet, and New Leeds for extensions and also to construct transformer chambers in Roundhay-road and Vicar-lane.

Aberdare.—The District Council have agreed to dissent from the scheme of the Aberdare Electric Lighting Company, Limited, for the electric lighting of the town, and a proposal will come before the next meeting to the effect that the Council themselves promote an electric lighting scheme.

Lyndhurst.—Application is being made by the Lyndhurst Electric Lighting and Traction Company, Limited, for a provisional order. It is proposed to lay cables in the High-street, Gosport-lane, Romsey-road, Welland's-road, Empress-road, Queen's-parade, and Pemberton-road.

City.—At last night's meeting of the Court of Common Council the Streets Committee reported on the practicability of generating electricity from steam raised by burning the City's refuse. The committee recommended that, as the lease of Letts's Wharf has so short a time to run, it will be inexpedient to sink further capital at the wharf.

Aston.—In the recent loan applied for we note that £11,800 of the sum required was for the hospital and its equipment, and providing for laundry plant and electric energy and lighting for both the small-pox and fever hospitals. This sum includes the following sums: laying down of electric plant, £1,800; and for a telephone, £530.

Radstock.—The Urban District Council have resolved to engage an engineer at a fee not exceeding 25 guineas—provided the Midsomer Norton Council would pay half the expense—to report upon the advisability of (*a*) lighting Radstock by electricity, (*b*) lighting Midsomer Norton by electricity, (*c*) lighting both the said urban districts by a joint electric scheme.

Llandudno — The Public Works Loan Commissioners have declined to give their consent to the unexpended balance (£1,045) of the loan for refuse destructor being applied towards the excess expenditure on the electric light loan, but the Local Government Board are prepared to sanction a loan of that amount for purposes of electric lighting, and the requisite application will now be made.

Glazing.—We learn that Messrs. Helliwell and Co., Limited, Patent Glazing and Roofing Works, Brighouse, are engaged upon the execution of various contracts for new tramway schemes, which include glazing car sheds, etc., at the London United depôts, Acton and Chiswick; East Ham borough electric works; Bristol depôts at Bedminster and Brislington; Sunderland, Aberdeen, Glasgow, etc.

Bermondsey.—The Council have granted an application from the London Electric Supply Corporation asking that the customary month's notice might be waived in reference to supplying electricity to premises in Southwark Park-road, as the tradesmen concerned might be placed at great disadvantage by waiting. The Council have added a rider to the effect that in future the full period of notice would be demanded.

Luton.—The Town Council have obtained a loan of £26,000 from private parties, at £3. 5s. per cent., for a term of 25 years, the capital to be repaid at the end of such term, the town clerk making provision for such repayment by way of a sinking fund, the interest to be paid half-yearly. The annual repayment of the fund amounts to £1,130. 8s. 8d. The question of arc lamps, meters, etc., will be considered shortly.

Christmas Number.—We have received the Christmas number of the *Illustrated English Magazine*, which consists of a double number of the usual type of this excellent publication. The stories are freezingly appropriate of Yuletide, ghosts and Arctic yarns vying with each other to produce that pleasant effect so well known by the reader of gruesome tales who is himself safely installed in a comfortable chair by the side of a roaring fire.

Chiswick.—At the last meeting of the District Council the surveyor reported that the poles on the Homefields recreation ground and Turnham Green Common had not been removed. The clerk was directed to write to the National Telephone Company, Limited, calling their attention to the matter, and asking for an explanation of the reason for the non-compliance with the notices served upon the company requiring the removal of the poles.

Cricket Club Dinner.—The first annual dinner and concert of the Brighton Corporation Electricity Works Cricket Club was held last week at the Cricketers' Hotel, Black Lion street, when a company numbering about 40 members and friends sat down. Mr. J. Christie, resident engineer of the electricity works, presided, and the vice chair was occupied by Mr. G. Goodall. After dinner an attractive musical programme, interspersed with toasts, was carried out.

Melrose.—The draft agreement between the Burgh Commissioners and Messrs. Crompton and Co. provides that the company lay the electric light as far as The Avenal, round by Ormiston-terrace, Buccleuch-street, and as far as the railway bridge. They will also extend the connection through Darnick on condition that the Waverley Hydropathic become consumers, and they will include Dingleton on condition that the asylum be secured as a customer.

Lancaster.—Colonel Slacke, R.E., held an unopposed enquiry on the 27th inst into an application by the Corporation for sanction to the borrowing of £14,700 for the provision of refuse destructors. It is proposed to use the steam generated for the boilers at the electricity works, which immediately adjoin the suggested site, and the engineer calculated that the amount of refuse which would be burnt would produce 4,500lb. of steam per hour, equivalent to 225 h.p.

Brighouse.—The Corporation propose to establish new electricity works, combined with a refuse destructor. Some years ago the Corporation bought out a private electrical venture and obtained a provisional order authorising them to make and supply electricity. These works have proved inadequate to meet the demand, and a scheme prepared by Messrs. Lacey, Clirehugh, and Sillar for the construction of new works, combined with a refuse destructor, at an estimated cost of over £20,000, has been adopted.

Wood Paving Blocks.—At the new public works depôt in Harrowby-street Docks, Cardiff, which is being erected for the Cardiff Corporation and is nearing completion, an extremely compact little plant has been installed for cutting blocks for wood pavement for the public streets. From 7,000 to 8 000 blocks can be cut in a day, or about 32 per minute, by a Temperley patent block-cutting saw supplied by Messrs. Ransom and Co., Chelsea. This is worked by one of Ruston and Proctor's 14 h.p. undertype engine and boiler combined. There is also a "thicknessing" machine, whereby uniformity of thickness in the planks is ensured.

Midland Electric Power Distribution, Limited.—Amongst the proposed Bills there is an application by the Midland Electric Corporation for Power Distribution, Limited, of Liverpool, for a provisional order under the Electric Lighting Acts for the extension of the area of supply, which will include additional districts and parishes in the counties of Stafford and Worcester. The districts of the Urban Districts Councils of Perry Barr and Tettenhall will be included. Among other streets and places the undertakers propose to lay electric lines within a specified time along Tettenhall Wood road, from Werge-road to School lane, Tettenhall Wood; and along Compton-holloway, from Tettenhall Wood-road to the bottom of Finchfield-hill.

Berkhampstead.—The report on electric lighting, adopted by the Urban District Council last week, concludes as follows: "After fully considering all the local circumstances, the committee were of opinion that in the interests of the district it would be well for the Council to obtain a provisional order at the earliest opportunity. As, however, the necessary notices could not be given in time for the next session of Parliament, and as the term of office of the whole of the present Council expires in April next, the committee suggested that the matter be referred to the new Council at its first meeting, so as to enable the proper notices being given for the ensuing session should that Council determine to carry out their recommendation."

Brighton.—A sub committee of the Telephone Committee has been appointed to report on a suitable site for telephone offices. At the meeting of the Town Council on Thursday last week a report was adopted from the Lighting Committee recommending that 107 arc lamps be erected along the tram routes, and wherever possible the standards for the tram wires be used to carry the lamps. The increased cost per year will be £1,431. The cost of the lamps was given as £6,400. The committee also recommended that all consumers agreeing to pay £1 extra a year may have their demand indicators cut out out all day on Sundays and on weekdays except during the ordinary hours of lighting—viz., from dusk till 10 p.m. During the debate which ensued reference was made to the charges for the Pavilion light, which worked out practically at 7d. per unit, and it was urged that the price could be reduced if the committee would only use the electricity for illuminating the grounds for the promenade concerts.

New Companies.—The following new companies have been registered: Ross Electric Light and Power Company, Limited; capital £8,000, in £1 shares.—French Electric Lighting Boards, Limited; capital £4,000, in £1 shares.—Perfect Light Company, Limited; capital £25,000, in £1 shares (object being to adopt an agreement with the Scott Snell Phillips Syndicate, Limited, and M. Lachman, etc.).—Greenall's "Positive" Meter Syndicate, Limited; capital £20,000, in £1 shares (object being to adopt an agreement with J. Greenall, etc.).—Imperial Electrical Supplies Company, Limited; capital £50,000, in £1 shares (object being to adopt an agreement made by this company with G. Bargate, G. S. Hertslet, H. W. Knott, E. P. Harvey, and J. L. Bell, etc.).—Horsehay Company, Limited; capital £100,000, in £10 shares (object being to adopt an agreement made by this company with H. C. and A. Simpson for the acquisition of the business of engineers, etc., as now and hitherto carried on at Horsehay Works, Horsehay, Salop, etc.).

Durham Power Scheme.—A company is being formed by local men in South Durham, West Durham, and Cleveland for the formation of an electrical supply company, and the promotion of a Bill in Parliament in their behalf to enable them to take up this task. It is reported that the following names are amongst the promoters: Messrs. Hugh Bell, A. J. Dorman, H. Pike Pease, M.P., J. Torback, J. Walton, M.P., E. R. Whitwell, W. Hustler Hopkins, E. Lloyd Pease, Sir Thos. Wrightson, M.P., and the representatives of Pease and Partners, Limited, Consett Iron

Digitized by Google

Company, H. Stobart and Co., W. Whitwell and Co., Skinningrove Iron Company, and many others. The area to be taken in under the scheme is very extensive, but will be easily covered when it is pointed out that from four central stations the power will be distributed, each station capable of transmitting the electrical energy 20 miles. The Bill which is being promoted in Parliament is similar in essence to one put through by South Wales last session, and the Board of Trade in that case settled protective clauses which were inserted in the Bill. Messrs. Lucas, Hutchinson, and Meek, of Darlington, and Messrs. Jackson and Jackson, of Middlesbrough, are the solicitors.

London County Council.—At Tuesday's meeting the Highways Committee reported that the arc lamps for the installation of electric lighting on Westminster Bridge and the Victoria-embankment would shortly be required, and tenders for the supply of these were invited by public advertisement. The tenders received, and which were referred to them by the Council on Nov. 13, were as follows: Gilbert Arc Lamp Company, £2,209. 18s. 6d., or, with certain modifications of the specification, £2,515; New Century Arc Light Company, £2,330; Crompton and Co., £2,598; Oliver and Co. (alternative), £2,910. 11s. 6d. or £2,676. 2s.; Verity's, Limited, £2,959. 12s.; General Electric Company, £3,320. The Gilbert Arc Lamp Company submitted, in addition to its tender strictly in accordance with the specification, two modified proposals—namely, for the use of (*a*) split globes at a cost of 30s. each extra for the parapet lamps; and (*b*) specially long carbons at an extra cost of 50s. each for the kerb lamps. The engineer states as regards proposal (*a*) that split globes were not specified, as they are not in general use, but that the adoption of them would facilitate the trimming and cleaning of the lamps, and that the extra cost would be about £105. As regards the proposal (*b*) the engineer states that probably a considerable saving would be effected in the cost of trimming, although some loss might arise from breakage through the use of such long carbons, and that the extra cost if the proposal were adopted would be about £200. The engineer was of opinion that the advantages to be gained by the adoption of both proposals would justify the increased expenditure, and the committee recommended the acceptance of the Gilbert Arc Lamp Company with the modification as suggested. The report was agreed to.

Colonial.—We are indebted to the *New South Wales Railway Budget* for the following interesting information: With a view to increasing the electric power at North Sydney, and for the purpose of providing a reserve for use in times of emergency or extra strain, an extensive battery is being constructed at the power-house, Ridge-street, North Sydney. The battery, when completed, will be one of the largest in the colony, and will contain no fewer than 260 cells. The accumulated power thus provided will form a useful auxiliary to that supplied direct from Ultimo, and will enable the management to cope with the ever-increasing demands of the district by allowing additional trams to run over the various lines, and relieve the great pressure at present experienced. With the completion of the Spit tramway, and other lines on the north side of the harbour proposed to be constructed, a considerable increase in electric power will become necessary. The main power is drawn from Ultimo, in addition to which there are batteries at Mosman, Flat Rock, and the one in course of construction.—Some difficulty has arisen between the Auckland City Council and the Auckland Electric Tramway Company, of London, owing to the company asking for an extension of time before proceeding with the work. At a meeting of the Council, the Mayor explained that if the tramways were not started within 12 months from June, 1900, the Government had the power to revoke the Order in Council. By the agreements the company had to lay the permanent way within 12 months from June, 1900, and complete the work by June, 1902. If the permanent way was not laid within the specified time, the company forfeited its deposit of £1,000. After some discussion, the Mayor was authorised to send the following cable to the company in London: "That the Council will not consent to any alteration in the time fixed by deed for the completion of the various works therein specified."—It is reported that Mr. W. G. Bingham has cabled to his attorney in Adelaide, asking him to intimate to the City Council that he is prepared to release them unconditionally from their agreement with him respecting the electric tramways, but he considers that the Council are bound by their honour to advocate his claims for obtaining a similar contract with any trust that may be formed.

PROPOSED NEW BILLS.

(*Second List.*)

The following notices of intention to apply for Bills have appeared in the *London Gazette*:

Electric Tramways and Railways.—Electric railway (South-Western and Isle of Wight Junction Railway); Victoria, City, and Southern Electric Railway (company); Finchley and Hendon (company), Kingston-on-Thames (Corporation), Tyneside (company), Wigan (Corporation), Metropolitan and District Railway (British Westinghouse Company), Manchester and Liverpool Electric Express (company), Swindon (Corporation), Littleborough (U.D.C.), London United Tramways (company), South Lancashire (company), Central London Railway (company), West Riding (United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited), King's Norton and Northfield (U.D.C.), Scarborough (company), West Cumberland (company), City and South London (company), Liverpool (Corporation), Worcester (Worcester Tramway Company, Limited), Folkestone (Corporation), Metropolitan and Metropolitan District Railway (British Westinghouse Electric Company), Leeds (Corporation), Derby (Corporation), City and West end Railway (company), Bexley (U.D.C.), Wimbledon (U.D.C.), Brompton and Piccadilly-circus Railway (company), Weston-super-Mare (Weston-super-Mare and District Electric Supply Company), City and North-East Suburban Electric Railway (company), Middleton and Chadderton (Corporation and U.D.C.), Crompton (U.D.C.), Dover (Corporation), Gosport (Portsmouth Street Tramways Company), Shipley (U.D.C.), Leamington (Leamington and Warwick Tramways and Omnibus Company, Limited), Pontypridd and Rhondda Valley (British Electric Traction Company), Birkdale (U.D.C.), King's Head Railway (company), Piccadilly and City Railway (company), Charing Cross, Hammersmith, and District Electric Railway (company), West and South London Junction Railway (company), Watford and district (company), Royton (U.D.C.), North-East London Railway (company), Manchester (Corporation), Portmadoc, Beddgelert, and South Snowdon Railway (Northern Counties Traction Company), Pontypridd (U.D.C.), Gateshead and district (company), Folkestone, provisional order (Corporation), City of Birmingham Tramways (company), Charing Cross, Euston and Hampstead Railway (company), Cheriton Tramways (U.D.C.)

Electric Lighting.—Crawley, electric light powers (Crawley Gaslight Company, Limited), Richmond (Richmond Gas Company), Foots Cray (Kent), (Bromley R.D.C.) Carnarvon and district (E. W. I. Peterson), Trowbridge (U.D.C.), S. York, electric power (company), Aberdare (company), St. Austell (company), Hoddesdon (U.D.C.), Ware (U.D.C.), Dorchester (Corporation), Workington (Corporation) East Cowes (Isle of Wight Electric Light and Power Company, Limited), Crompton (U.D.C.), Hampton (U.D.C.), Tredegar (U.D.C.), Mitcham (Croydon R.D.C.), Honley (U.D.C.), Pokesdown (Bournemouth and Poole Electricity Supply Company, Limited), Benwell and Fenham (U.D.C.), Dover, electricity supply (Corporation), Marylebone (Marylebone Electric Supply Company), Barry (U.D.C.), Teddington, Hampton, Hampton Wick, and Ham (Richmond, Surrey, Electric Light and Power Company), Shildon (Northern Counties Electric Supply Company), Handsworth (Northern Counties Electric Supply Company), Benfield Side (Northern Counties Electricity Supply Company), Consett (Northern Counties Electricity Supply Company), Annfield Plain (Northern Counties Electricity Supply Company), Norton (Northern Counties Electricity Supply Company), Thornhill (Northern Counties Electricity Supply Company), Heston and Isleworth (Richmond, Surrey, Electric Light and Power Company, Limited), Sittingbourne (County of Kent Electrical Power Distribution Company, Limited), Goole (U.D.C.), Alnwick (Northern Counties Electricity Supply Company), Harpenden (Harpenden Gaslight and Coke Company, Limited), Neath, Briton Ferry, and Aberavon (Electric Power Distribution Company, Limited), Pickering (Northern Counties Electricity Supply Company), Midland Electric Power Distribution Corporation, Pudsey (Corporation), Bromsgrove (C. Steer and others), St. Marylebone (B.C.), Macclesfield (Electrical Power Distribution Company, Limited), Dorking (Surrey Electrical Power Distribution Company, Limited), Stoke Newington (North Metropolitan Electrical Power Distribution Company, Limited), Neath (R.D.C.), Rickmansworth (North Metropolitan Electrical Power Distribution Company, Limited), Frome (U.D.C.), Wellingborough (U.D.C.), Cannock (U.D.C.), Pontypridd (U.D.C.), Todmorden (Corporation), Newbury (Urban Electric Supply Company, Limited), Warwick (British Electric Traction Company, Limited), Worsley (U.D.C.), Isle of Thanet (Isle of Thanet Electric Tramways and Lighting Company, Limited), Llandaff and Dinas Powis (R.D.C.), Deptford (County of London and Brush Provincial Electric Lighting Company), Rishton, Great Harwood, and Clayton-le-Moors (C. Chadwell), Barrow-in-Furness (Corporation), Mansfield (Corporation), Arlesey (company)

Tram and Electricity.—Stalybridge, Hyde, Mossley, and Dukinfield Tramways and Electricity Board (Corporations).

Electric Power Supply.—Yorkshire (company), Derbyshire and Nottinghamshire (company), Cleveland and Durham County (company).

Various.—The following proposals are included in omnibus Bills: Eccles, tramway, electric light (Corporation), Blackburn, electricity supply (Corporation), Willesden, tramways (U.D.C.), Bradford, tramways (Corporation), Tottenham, railway extensions (Tottenham and Hampstead Junction Railway Company), Brighton, electric apparatus, tramways, improvements, etc. (Corporation), Bournemouth, tramways (Corporation), Burton-on-Trent, tramways (Corporation), Handsworth, electric tramways and lighting (U.D.C.), Bolton, tramways (Corporation). Lowestoft, electric tramways, lighting, extensions, etc. (Corporation) Kingston-upon-Hull, tramways electric power (Corporation), Smethwick, electric supply and tramways, etc. (Corporation), Blackpool, new tramways (Corporation).

PROVISIONAL PATENTS, 1900.

NOVEMBER 19.

26853. Improvements in and relating to arc lamps for projection purposes. Charles Vickery Drysdale, Clairville, Hadley-road, New Barnet, Herts.

Digitized by Google

20868. Improvements in electric lamps for use in photography. Jean Schmidt, 18, Buckingham-street, Strand, London.

20870. Improvements in electrical signalling for railways. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Leone Olper, Italy.)

20873. Improvements in the manufacture of carbons for electrical and other purposes. Henry Richard Gregory, 55, Chancery-lane, London.

20878. Improvements in telegraphic receiving and translating arrangements. Alexander Muirhead, 323, High Holborn, London.

NOVEMBER 20.

20926. Improvements in electric arc lamps. Crompton and Co., Limited, Sidney Linton Brunton, and Arthur John Hodgson, Arc Works, Chelmsford. (Complete specification.)

20929. Improvements in phonographs and the like instruments. Wilhelm Peisker, Fritz Schlomka, and Herrmann Kautz, 70, Deansgate, Manchester. (Complete specification.)

20931. An improved method of illuminating dining tables and the like by electricity. Herbert Edward Evans, High-street, Woodford Green, Essex.

20938. Improvements in or applicable to the diaphragms or membranes of phonographs and the like instruments Wilhelm Peisker, Fritz Schlomka, and Herrmann Kautz, 70, Deansgate, Manchester. (Complete specification.)

20942. Improvements in systems of motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William B. Potter, United States.) (Complete specification.)

20943. Improvements in safety devices for electric motor control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Maxwell W. Day, United States.) (Complete specification.)

20945. Improvements in electric telegraphs. Charles Adams-Randall, 98 Prince of Wales-mansions, Prince of Wales-road, London.

20946. Improvements in electric telephony. Charles Adams Randall, 98, Prince of Wales-mansions, Prince of Wales-road, London.

20960. Reversible galvanic cells or so-called storage batteries. Thomas Alva Edison, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

20961. Improvements in electric cables. David Cook, 70, Palace-chambers, Westminster, London.

20967. Improvements relating to incandescent electric lamps. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Peyton Pinckard, United States.)

20982. Improved construction of electric meter. Frank Moore, 166, Fleet-street, London.

NOVEMBER 21.

20995. Improvements in poles for electric railways, electric lights, and telephone and telegraph lines. Edward Wellman Serrell, 33, Chancery-lane, London. (Complete specification.)

21004. Improvements in primary batteries. Robert Frederick Hall, 24, Temple-row, Birmingham.

21017. Improvements in typewriters and in printing telegraphs. James Dundas White, Fairfield, Redhill, Surrey.

21022. Improvement relating to the excitation of the field magnets of electric generators and electric motors. John Rutherford Blaikie, Electric Lighting Station, Penrose-street, Walworth, London.

21025. Improvements in electric railway systems and switches therefor. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (Frederick W. Hild, United States.) (Complete specification.)

21026. Improvements in electric railway systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William B. Potter, United States.) (Complete specification.)

21027. Improvements in ground detectors for electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William H. Pratt, United States.) (Complete specification.)

21028. Improvements in electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Philip Farnsworth, United States.) (Complete specification.)

21029. Improvements in tachometers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Caryl D. Haskins, United States.) (Complete specification.)

21030. Improvements in electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William B. Potter, United States. (Complete specification.)

21036. Improvements in switches for electric lamps and the like. Henry Max Salmony, 226, High Holborn, London.

21031. Improvements in systems of electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon street, London. (Albert H. Armstrong, United States. (Complete specification.)

21042. Improvements in electric arc lamp carbons. Thomas Archer Rose and Albert Barnes, 9, Adam-street, Strand, London.

NOVEMBER 22.

21086. Improvements in electrical ceiling roses for suspended and like fittings. George Sperryn and William Henry Wood, 104, Colmore-row, Birmingham.

21100. Improvements in or applicable to electric converters or transformers. Joseph Platt Hall, 70, Deansgate, Manchester.

21135. Improvements in the manufacture of plates for secondary batteries. Theodore Pescatore and the Tudor Accumulator Company, Limited, 322, High Holborn, London.

21144. Improvements in electric motor starting apparatus. William Watson and Edwin Preece, 24, Southampton-buildings, Chancery-lane, London.

21149. Electrolytic process for the precipitation of metals and alloys from their solutions, as also for the deposition of metals or alloys on other metals or alloys or on other substances. Jules Meurant, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

NOVEMBER 23.

21179. Improvements in telephone switch jacks. Alfred Whalley, Ashville, Helsby, near Warrington.

21180 An excess electric current indicator, controller, and cut-out. Percival John Pringle, Morningside, Sidcup, Kent.

21182. Improvements in gas pendants, chandeliers, electroliers, and the like. Millicent Frances Hawkes, of Thrift and Enterprise Company, 24, Temple-row, Birmingham.

21196 Improvements in marine electric light fixtures and switches therefor. George Lincoln Martin, 13, Park-row, New York, U.S.A.

21216. Improvements in method of graphitising electrodes. Philip Middleton Justice, 55, Chancery-lane, London. (The International Acheson Graphite Company, United States.) (Complete specification.)

21217. Improvements in current regulators. Philip Middleton Justice, 55, Chancery-lane, London. (The Erie Exploration Company, United States.) (Complete specification.)

21223. Improvements in or relating to electrodes or the wires or conductors connected thereto in electrolytic cells, meters, or other electrolytic apparatus. The Bastian Meter Company, Limited, and Charles Orme Bastian, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

21233. Improvements in secondary batteries. Theodore Pescatore and the Tudor Accumulator Company, Limited, 322, High Holborn, London.

NOVEMBER 24.

21252. Improved means of eliminating and retarding certain electric and other rays for surgical, medical, and other purposes. Charles Morley Johnson, Denmark House, Redhill, Surrey.

21255. Improvement in methods of jointing electric conductors. C. V. de Falbe, trading as the Electrical and General Contracting Company, and Thos. Harden, 17, Shaftesbury-avenue, London.

21292. Improvements in means for obtaining magnetic adhesion of locomotives or motorcars in electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The Union Elektricitäts-Gesellschaft, Germany.) (Complete specification.)

21293. Improvements in insulated electric conductor and method of making the same. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

21294. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

21304. Improvements relating to electric meters. Fritz Lux, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21311. Improvements relating to electric traction. Harold Charles King, 27, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Dec. 15.

1899.

23141. Controlling arrangements for switches for direct-driven cage hoists and general electric and motor work. Goddard.

Digitized by Google

16899. Electrical transformers. Berry.

23153. Switches for use with rheostats for starting and controlling electric motors for lifts or the like. Hirst and Hunt.

24567. Controlling apparatus for electric lifts and other electric machines. Stevens, Major, Stevens, and Stevens.

24701. Manufacture of submarine electric conductors. Siemens Bros. and Co., Limited, and Dieselhorst.

24833. Recording and reproducing arrangement for phonographs, graphophones, and other machines for reproducing speech and the like. Grivolas.

25275. Clock-controlled electric switches. Webster.

25429. Alternating-current induction motors. Lamme. (Date applied for under International Convention, May 24, 1899.)

25509. Methods or means of insulating electric wires. Hodges, Smith, and Burrows.

25741. Lightning arresters. Wurts. (Date applied for under International Convention, June 8, 1899.)

1900.

466. Apparatus for facilitating the escape of gas from electric storage batteries or accumulators. Wells and Allan and Adamson, Limited.

758. Controlling devices for the motor circuits of electrically-propelled vehicles. Wetter. (Elektrizitäts-Aktiengesellschaft, vorm. Schuckert und Co.)

1024 Electrical switches. Heywood and Heywood.

1267. Permanent way for tramways and points therefor, specially applicable to electric tramways. Brodie.

1531. Electric light dimmer. Hatmaker.

3031 Electricity meters. Little.

3501. Electric alarums. Hill.

5528. Electric accumulators. Gumiel.

11438. Casings for the jointings of underground electrical cables. Siemens Bros. and Co., Limited, Dieselhorst, and Budd.

11944 Switching arrangement for Nernst and vacuum incandescence lamps. Feeny. (Allgemeine Elektricitäts Gesellschaft.)

13356. Telephonic repeaters. Thompson. (Tice, Urmson, Parsons, and Bell.)

15774. Electric signalling apparatus for fire-alarm and other purposes. Clar.

16699. Lightning arresters. British Thomson-Houston Company, Limited. (Bell.)

17119. Arrangement of connections for sets of electric glow lamps in series so as to maintain the circuit in case of the extinction of one or more of the lamps. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

18089. Electrically-driven road vehicles. Porsche.

18451. Circuit controller for electric street railway cars and other uses. McCallum.

NOTES.

Electric Pumps.—A report of the commissioners connected with the branch of the South Staffordshire mines refers to the fact that electric pumps are to be largely used in the future in various operations in that district.

African Telegraph Lines.—Amongst the German Government estimates for 1901 is an item for £10,000 towards the expense connected with the beginning of the telegraph line which will connect Dar Es Salam, in German East Africa, with Lake Tanganyika. This line will eventually join the Cape-to-Cairo wire. At present, however, it is only intended to push on with the line to Mpapua, a distance of about 270 miles from the coast.

South London Electric Railway Accident.—The Board of Trade report on this accident shows that it was due to a driver running past the signal at danger. This is another case illustrating the need of providing a safeguard by which drivers will be informed if they do not implicitly obey the signal given. If an electric railway is provided with both compressed air and magnetic brakes, the switching off of the current on the third rail could, when the signal is at the "danger" position, easily be arranged to do this.

Electricity and Mining.—It is reported from Rossland British Columbia, that the electrical power company at Kootenau River which supplies the Rossland mines, has found it worth their while to extend their plant in order to meet the increased demand for power for all purposes at these gold mines. The amount to be expended in new plant is about £400,000, and this should enable the company to give a full and sufficient power supply to all who require it. A hoist having some 1,000 h.p. was to have been installed during the past week, and it is expected that much benefit will be derived from its use.

The Electric Eel.—The following is the catastrophe referred to by one of the speakers at the Institution dinner on Monday last: At the Zoological Gardens, London, recently, a large electric eel was swimming in its tank with more activity than usual when a big foreign cockroach dropped into the water. It began to swim vigorously across the tank, spreading out its wing cases and making a disturbance on the surface of the water. The eel turned round, swam past it, discharged its battery at about 8in. off, and the cockroach instantly stopped stone dead. The eel afterwards swallowed it.

Aberdeen Tramways.—Aberdeen is likely to have an exhibition of the various ways in which electric tramways can be worked on the contact system. Two firms have already offered to equip experimental lines to display the advantages of their particular arrangements, and it is most likely that both of these will be accepted. The firm making the first offer was Messrs. McIlroy and Grunow, while the other system is the Johnson-Lundell, which Mr. Leonard W. Holmes wishes to introduce into Aberdeen. If all goes well, there will be an additional attraction to induce electrical engineers to spend their holidays in 1901 in Scotland.

Educational Articles.—Our American contemporary, *Electricity*, announces in its issue for Nov. 14 that a series of articles of an educational nature will be given week by week in its columns. Readers are warned that no "mathematical gymnastics" will be indulged in, which we presume would be paraphrased by Prof. John Perry to mean that the articles will be specially adapted to lazy engineers who will never excel. We agree with our contemporary, however, that it is, at the present time, much better to avoid in a technical journal higher mathematics as much as possible, in order to meet the reading capacity of the bulk of the readers.

Power Transmission in the Tyrol.—As in most countries where water power is available to any considerable extent, we find that electric power transmission is making rapid headway in the Tyrol. The latest proposal is to utilise a waterfall on the Stilluppback near Mairhofen. About 2,000 h.p. is available from this source, which it is proposed to convert into electrical energy for transmission to the neighbouring township, besides to some gold mines, and possibly to a railway now being built in the Ziller valley. The scheme is the outcome of private enterprise, and the whole of the work in connection with the same has been entrusted to Messrs. Otto Kury, München-Innsbruck.

The Electric Shunting Pole.—We gather from the daily Press that a Glasgow gentleman has recently devised a means of making the shunting work which has to be done by many railway servants somewhat more safe. The idea consists of a combination of an electric lamp with the shunting pole, so that when the man is operating the couplings he can for the time being light up the space between the railway trucks. A switch in the handle of the pole is arranged somewhat after the manner of a switch in a telephone receiver, so that the small accumulator is only discharged through the lamp when the light is required. By means of red and green glass respectively the pole can also be used for signalling purposes.

The Nernst Lamp.—At a recent meeting of the Frankfort-on-the-Main Association of Electrical Engineers, Herr Wolff, manager of the Frankfort branch of the Allgemeine Elektricitäts-Gesellschaft, showed and explained the working of a new form of Nernst lamp. The necessary initial heating of this lamp is effected by a spiral of platinum embedded in some fireproof composition. By means of a switch neatly concealed within the base of the lamp, this spiral is automatically cut out of circuit after the lamp has been rendered sufficiently conductive by the imparted heat. The lamp exhibited was of 25 c.p; hitherto no lamps of the Nernst type for lower candle-powers have been constructed.

Personal.—We have to congratulate the directors and shareholders of the Central London Railway in that they have succeeded in securing the services of Mr. P. D'Alton as engineering chief of their line. Mr. D'Alton's experience in general engineering has been most extensive, and his period of command of the Deptford station of the London Electric Supply Corporation gave him an intimate acquaintance with the worst side of electrical engineering. Mr. D'Alton for several years was connected with the most successful attempts which have ever been made in connection with submarine vessels, and these, we presume, are in some way a recommendation for managing a railway line which runs in the depths of the earth. We wish him every success in his new post, and are sure that his appointment will conduce to the economical working of the system.

Electrical Engineers Volunteers. — The South African contingent of the Electrical Engineers (Royal Engineers) Volunteer Corps will find a warm reception awaiting them on their arrival in England. The welcoming ceremonies commence on Saturday, the 15th inst., when the detachment will be entertained at dinner by the other members of the corps. Then on Monday, the 17th inst., another welcome-home dinner will be held in the Prince's Restaurant, under the presidency of Prof. Perry. On the

Digitized by Google

next night we are informed that the Institution of Electrical Engineers are arranging a reception to be held at the Covent Garden Opera House, which has been generously placed at their disposal by Mr. Rendle and Mr. Forsyth for this purpose. On this occasion ladies will be invited, and we trust that the Electrical Volunteers will not be unduly embarrassed by the welcome from the fair sex.

Import Duties.—The success of the airship of Count Zeppelin has induced other inventors to state in the daily papers how successful they are sure they could be if they had the requisite opportunities. One of these inventors, hailing from Italy, states that he will be building an airship next February or March, and that he is now in negotiation with important builders with regard to its construction. He also states that it will be built in Italy to avoid import duty. We were not aware that the building of airships was already a recognised profession, and should think that in any case an airship would give one of the best opportunities of avoiding import duty. When our coastguards are expected to guard against smuggling, their task is rendered possible by the limited number of landing places, but this does not apply to an airship, which should result in considerable trouble to the Customs officials.

Light Railway Procedure.—A curious point was recently raised in connection with the procedure of the Light Railway Commissioners before Sir Courtenay Boyle. An order was practically agreed to by the Commissioners in 1897 subject to certain additions being made to the scheme, which were not complied with till 1899. In the meantime a firm had acquired some scheduled property, and had converted the same into a recreation ground for their workpeople. When the case was heard this firm had no opportunity of protesting, in spite of the fact that a large outlay would be rendered almost valueless if the scheme were proceeded with on the original lines. Sir Courtenay Boyle's solution of the difficulty was that the parties affected should meet and arrange the matter mutually. It is evidently unfair that the Commissioners should hang up a scheme for two years and then give a decision without the interested parties being heard.

Cork Foundations.—In Germany cork is said to have been used with success in isolating the vibrations and consequent noise caused by machines installed in or near dwelling-houses. A sheet made up of flat pieces of cork in mosaic fashion of corresponding size to the bed-plate of the machine, and held together by an iron frame, is laid under the machine. The source from which we gather this information also alludes to the isolation, by means of cork, of each bolt or connection between the bed-plate of the engine and its foundation, but does not describe in what manner such isolation is effected. It is, of course, apparent that the mere sandwiching of a sheet of cork between the bed-plate of a machine and its foundation would not necessarily absorb troublesome vibrations, since each anchor bolt is a medium whereby the vibrations of the engine may be transmitted to its foundation, and hence to the floor and walls of the building unless effectively isolated from the same. How this effective isolation is obtained by the use of cork sheeting remains to be explained. For our part, we should be more inclined to rely upon a specially-prepared foundation of extra area and solidarity and to a careful balancing of the reciprocating parts of the machine.

Royal Institution.—The following are the lecture arrangements at the Royal Institution before Easter: Sir Robert Ball, six lectures (adapted to young people) on "Great Chapters from the Book of Nature"; Prof. J. A. Ewing, six lectures on "Practical Mechanics (experimentally treated), First Principles and Modern Illustrations"; Dr. Allan Macfayden, Fullerian Professor of Physiology, R.I., four lectures on "The Cell as the Unit of Life"; Dr. Arthur Willey, three lectures on "The Origin of Vertebrate Animals"; the Rev. H. G. Graham, three lectures on "Society in France before the Revolution"; Sir Wyke Bayliss, two lectures on "Shakspear in Relation to his Contemporaries in Art"; Prof. R. K. Douglas, two lectures on "China"; Mr. F. Corder, three lectures on "Vocal Music: its Growth and Decay" (with musical illustrations); the Right Hon. Lord Rayleigh, six lectures on "Sound and Vibrations." The Friday evening meetings will begin on Jan. 18, when a discourse will be delivered by Prof. Dewar on "Gases at the Beginning and End of the Century"; succeeding discourses will probably be given Dr. A. W. Ward (the Master of Peterhouse), the Right Rev. Monsignor Gerald Molloy, Prof. G. H. Bryan, Prof. J. J. Thomson, Sir W. Roberts-Austen, Mr. H. Hardinge Cunynghame, Mr. W. A. Shenstone, Dr. Horace Brown, the Right Hon. Lord Rayleigh, and other gentlemen.

Advantages of Electric Traction.—The advantages of electric traction for suburban or local railways are summed up by a Bohemian authority somewhat as follows: The principal advantages of electric traction consist in that a lighter type of rail, and, moreover, bridges of lighter construction, may be employed; many of the existing arrangements at stations are rendered unnecessary, while station platforms may be considerably shortened; and, lastly, heavier gradients and curves of smaller radii allowed, whereby considerable saving in excavations, etc., may be effected. It is pointed out that a serious drawback hitherto experienced has been that the cost of constructing local lines is scarcely less per mile run than that holding for main-line work, nor is the subsequent cost of working the same much less in comparison. It is therefore necessary to adopt means of communication, the initial outlay on which and subsequent cost of working are in better unison with the financial means locally available. In order to make a success of local lines in Bohemia, it is therefore recommended that attention should be turned to light railways of normal gauge, the cost of which, in comparison with main-line work, would be considerably less. Above all, the possibilities of electric traction should be kept in mind. If the above advice is acted upon, Bohemia should soon be added to the list of markets open to traction engineers and manufacturers.

Accumulators for Ships.—In a contribution to the *Elektrotechnischer Anzeiger* Mr. Fritz Forster discusses the use of accumulators for lighting purposes on ocean steamships. It appears that a German firm, who make a speciality of ship installations, have recently installed experimentally quite a number of batteries of accumulators in Hamburg ships. All these ships previously possessed generating plants, the dynamos being either shunt or compound wound machines. But in each case they were designed to yield only the normal difference of potential required for the lighting, whence it was necessary to provide for charging the accumulators, subsequently introduced, in two parallel batteries, in order to avoid essential modifications of the existing plant. The accumulators, fitted with acid-tight covers of vulcanite, were placed in a compartment as near the switchboard as possible in each case, and firmly secured. A diagram which accompanies the article shows the connections adopted to facilitate cutting out the compound winding of a dynamo when charging, so as to enable it to be run temporarily as a shunt-wound machine, whereby to avoid the danger of a back E.M.F. reversing its polarity. As the writer suggests, experience alone can prove the adaptability of accumulators for shiplighting purposes.

Digitized by Google

But it is not impossible that accumulators may play an important part in the future of this branch of electrical work, and they will be specially useful when a ship is in port and the boilers not under steam.

Accumulator Cars.—In discussing the capacity of batteries for electrically-propelled motorcars, our contemporary *L'Electricien* remarks that it is usual to adopt a battery consisting of 44 elements, which gives an available mean difference of potential at the terminals of about 85 volts. The mean output of energy per ton-mile of a well-constructed car is about 136 watt-hours, whence it follows that an average output of 1·60 ampere-hours per ton-mile may be relied upon. If we denote by m the ratio between the weight of the car under service conditions and the weight, P, of the battery—P being expressed in pounds—the total weight of the car will then be m P pounds. To accomplish a journey of M miles with this car, we must have 0·000643 m P M ampere-hours. On the other hand, if we denote by c the specific capacity per pound of a single element relative to the aggregate weight—the weight of the element being $\frac{P}{44}$—then the total capacity will be $C \cdot \frac{P}{44}$. In order that the car may accomplish M miles, we must have $C \cdot \frac{P}{44} = 0\,00071\ m\ P\ M$, whence we get the equations $C = 0315 \cdot m\ M$ and $M = \frac{31{\cdot}7\ c}{m}$, which enable us to determine the specific capacity requisite for a given number of car miles. Or, inversely, we may determine the number of miles which a car equipped with a battery of the given specific capacity will be able to accomplish. As a rule for an ordinary car $m = 3$, but for a car specially designed for racing m may be set down as 2. An ordinary car ($m = 3$), with a battery of 4½ ampere-hours capacity per pound of element, may have a range $M = \frac{31{\cdot}7 \times 4{\cdot}5}{3} = 47{\cdot}5$ miles. In order to accomplish a 150-mile run, a racing car ($m = 2$) must be equipped with a battery having a capacity per pound weight of each element of $C = {\cdot}0315 \times 2 \times 150 = 9{\cdot}5$.

The Dublin Conversazione.—On Thursday, Nov. 29, the Dublin Section of the Institution of Electrical Engineers held their first conversazione at the lecture theatre of the Royal Dublin Society. Those present were received by Prof. G. F. and Mrs. FitzGerald, and the proceedings, which were highly successful, comprised an exhibition of various electrical experiments and apparatus by members and others. There was also a short lecture on rotating magnetic fields, illustrated experimentally by the chairman, Prof. G. F. FitzGerald, F.R.S.; a similar lecture, illustrated by lantern slides, by Prof. W. F. Barrett, F.R.S, on the permeability of certain alloys of iron and steel. In addition there was an excellent short musical programme, and an exhibition of an Edison grand concert phonograph by Mr. J. Gibson. Among the very numerous exhibits may be specially mentioned a new form of meldometer, for determining the softening points of minerals, Dr. J. Joly, F.R.S.; the action of radioactive material on electric discharge, Dr. F. J. Trouton, F.R.S; frictional electrical machine, date very early in eighteenth century; original Page electromagnetic engine, exhibited in the Great Exhibition of 1851, A. E. Porte and J. R. Sykes; meteorological instrument with electrical recorders, A. Yeates; X-ray exhibition, Dr. W. Haughton; electric lamp (movable on rails), A. Guinness, Son, and Co., Limited; tramway and power distribution (material and instruments), A. Jacob; system of telephoning as applied to electric traction, J. Y. Fletcher; tram material as used in Dublin, J. W. Towle, R. H. Humphries, P. S. Sheardown, and S. G. Redman; various types of house meters, G. F. Pilditch.

Electrolysis by Alternating Currents.—In decomposing matters by means of electricity we have, remarks the *Elektrotechnische Rundschau*, to distinguish between direct and indirectly produced decomposition. In the case of indirect electrolysis, it is really the heat emitted by the electrically incandesced carbon rods or blocks which produces the decomposition. This fact renders it immaterial whether the heat be generated by alternating currents or by direct currents. But for direct electrolysis alternating currents are only applicable in certain cases. For instance, it is advantageous in nickel plating or coppering to reverse the direction of the galvanising current for a brief period at times, when it follows that the surface of the cathode—nominally the receiving portion of the combination—must become virtually the anode or giving portion during the reversal, thereby causing a modification of the molecular construction of its surface. It is evident that this process may, under certain circumstances, conduce to results which cannot, perhaps, be so satisfactorily effected by other means. But the combination of two direct currents so as to obtain successive impulses in opposite directions constitutes in reality a kind of alternating current, the individual phases of which are very long. This circumstance has been put to account by a Norwegian inventor, who proposes to employ for electrolytical purposes alternating currents of varying impulse lengths, so that the impulses given in the one direction have a greater influence on the electrolytic bath than those in the other. The desired result may be effected either by making the impulses in the one direction of longer duration than those in the other, or by giving them relatively greater current strength. As an alternative, both methods might be combined, or the potential allowed to increase as well as the current strength. In fact, many modifications are possible, experimental researches with regard to which may lead to useful results. The new process is undoubtedly worthy of careful consideration, especially in its possible adaptability for the electro-deposition of metals in any desired thickness without the fear of stripping.

Electricity as a Stimulus.—At a recent meeting of the Medico-Psychological Association of Great Britain and Ireland, Dr. H. Lewis Jones read an interesting paper upon the application of electricity in certain forms of mental disease. In view of the charges which had been brought by certain medical men against the extra pressure introduced into commercial life by the devices perfected by electrical engineers, it is interesting to note that electricity is able in certain cases to remove the mental diseases which indirectly it has helped to cause. In the paper in question Dr. Lewis Jones referred to the most fact that the important development of electricity in the last 10 years has been in the direction of general electrification for general effects, and this line of treatment has had the advantage of being very carefully worked out by a physiologist who is not at the same time a medical man, Prof. D'Arsonval. He has shown that a profound effect can be produced upon the general nutrition of the body in this way, and has established by measurement the increase of carbonic acid, of body heat, and of urea in animals and in people submitted to general electrification. Clinical experience has also demonstrated the immediate effect which follows general electrification in various forms of debility. The author proceeded to describe the way in which he recommended the electrical stimulus to be applied to patients who were suffering from overmentation, and quoted a number of cases in which most beneficial results had accompanied the treatment. Alter-

Digitized by Google

nating currents were largely employed in the cures, and the general effect is a stimulus, from which the appetite improves, the patient gains weight, and is able to sleep. Another doctor concurred with the author in his statements, while a question was raised by one member as to how far the water in the electric bath contributed towards the cure. We would suggest to central-station engineers that when they are feeling overworked they should bathe in the water-tank providing the artificial load for their station. The current passing through the body could then be varied by altering the angle between it and the general line of flow of the current. We are indebted to the *Lancet* for the abstract of Dr. H. Lewis Jones's paper.

Electric Travelling Cranes.—With respect to the largely increasing use of electric travelling cranes in factories and foundries, Mr. A. D. Williams, in a paper recently presented to the Pittsburgh Foundrymen's Association, gave some useful practical hints concerning these. Thus, he states that the electric motors, controllers, and wiring on cranes should be so placed as to be easily accessible for repairs. Good insulation on the conductors he considers to be a very important point, and one which should be insisted upon. Another matter which is important, and is stated at the same time to be one of the weak points of electric cranes, is the controller. In this, as with the motors, all parts should be easily accessible, and so arranged that those subject to wear can be removed and replaced with a minimum amount of trouble. The resistance coils should be arranged so that close control over the crane can be obtained, without which delicate handling is impossible. The device by which the operating levers are centered, or held in the position at which the current is off, should be so constructed that the operator is not likely to throw the lever too far and reverse unintentionally. Any weakness in this device is a great source of danger, but it is at the same time desirable to have easy working controllers. The electric motors should be enclosed in dustproof casings, and the author considers that it is very desirable to have all parts standardised to facilitate their renewal when worn. The armature and commutator should be easily removed, and he thinks that, although increasing the first cost somewhat, it is desirable to have a set of spare armatures added, as this may save delay at a very inopportune time. The use of an automatic or load brake is advised in preference to the magnetic brake, but careful and frequent examination of the brake is recommended in any case. Although the parts which go to make up a crane are not very numerous, Mr. Williams lays stress on the necessity for putting them up properly, and not anyhow. The selection of good girders is a very important item, and when selected great care should be taken to have these put up true and level. The author points out that the old jib crane, which is very useful for very heavy loads, should not be discarded on the advent of the electric travelling crane, but it should be supplemented in most instances by a number of light cranes so that the traveller can be used at its maximum efficiency on loads proportionate to its capacity.

Patent Office Practice.—An interesting patent issue is shortly to be tried in America, in which a Mr. G. B. Selden claims a royalty from practically all motor vehicles using hydrocarbon engines. The history of the patent issued to the gentlemen in question is an instance of the faulty patent laws in the United States. We understand now that the law by which Mr. Selden has reaped so much advantage was amended in 1897. According to the *Scientific American*, the record of the case in the Patent Office shows that Mr. Selden's first application for a road engine was made on May 8, 1879, and rejected on May 31 of that year. According to the then law, a patent application could not be considered to be abandoned unless two years had elapsed since the last official action. Mr. Selden proceeded to file an amendment on May 26, 1881, nearly two years later. A second rejection on June 17, 1881, was followed on May 15, 1883, by another amendment; and a third rejection on May 26, 1883, was met by an amendment filed on May 18, 1885. An official letter sent to Mr. Selden on June 15, 1885, was not acted upon until June 13, 1887, only two days before the expiration of the two years of grace allowed by the statute. Another rejection on June 21, 1887, was answered by a letter dated April 13, 1889, and by an amendment filed June 10, 1889. Mr. Selden was required on June 14, 1889, to furnish a "smooth copy" of the specification prior to issue; but although the application was otherwise ready for allowance, it was not until June 5, 1891, nine days before the statutory limit, that the substitute specification was filed. An official letter of July 1, 1891, demanded a new oath prior to issue, but it was not until June 28, 1892, that Mr. Selden obeyed the order. The case was then transferred to another examiner, by whom some of the claims previously allowed were rejected on July 29, 1893. The next amendment was filed on April 1, 1895. The patent was finally granted on Nov. 5, 1895, just at about the time when the motor carriage began to make its appearance in the streets of the large cities. All of the 19 original claims were cancelled. By his intimate knowledge of the law Mr. Selden managed to delay the granting of his petition over 14½ years, during which time he had an opportunity of amending and improving his schemes. A more unjust system could not be conceived, as the patent dates from the day of issue in America, and not from the day of application.

Shiplighting.—A long article in the *Elektrotechnische Zeitschrift* by Mr. Grauert deals with electrical installations on new ships of the German navy. It appears that in the German service separate lead and return wires have been generally adopted, concentric cables being used in the neighbourhood of the ship's compasses. Attempts to employ the ship's structure as a return have not conduced to successful results, and so far as large vessels are concerned, this practice has been entirely superseded. But in the case of new torpedo-boats, where economy in weight is a vital consideration, the practice still holds. In all places exposed to the danger of mechanical injury, such as the engine-rooms and stokeholds, lead-covered iron-armoured cables are employed, while elsewhere cables well insulated with rubber, but otherwise unprotected, except in some cases by thin rust-proof wire, are used. The wood casing formerly employed has been abolished, owing to its inflammability. Hitherto the telegraph and telephone cables have been of the lead-covered iron-armoured type, but the newest ships have been provided with a central subway, like a corridor, as well as side corridors below the armoured deck, which may be used for the electric cables, telegraph and telephone wires, etc., thereby avoiding all danger of mechanical injury to the same. Having regard to this, it is proposed to dispense with the steel armour in future, even for the lighting and power cables, retaining only the lead protection. The practice of soldering branch connections has also been discarded in favour of branch fuse boxes, in which the connections are made to terminal bars. These branch circuit boxes are made for two, three, four, six, and eight lamps. They are, of course, watertight. Their introduction seems to have been a complete success, facilitating as they do systematic supervision of the ship's wiring. Although slate is at present generally used for

Digitized by Google

switchboard bases in the service, it is interesting to learn that iron is proposed as a substitute, owing to the unavoidable breakages which occur. Small machine boards with iron bases have already been successfully introduced, but the difficulty of insulating the terminals and connections has hitherto prevented the adoption of the plan on a large scale. With the exception of the connections to the measuring instruments, all the switchboard connections on the "Fürst Bismark" were for the first time made with bare copper bars, whereby a neat, solid construction is obtained which is also accessible. The necessary protection against moisture is provided by enamel, which also serves to distinguish the poles, red and blue being used. This type of board is particularly advantageous where the available space is limited in depth, since the connections behind require no supervision, and the screw terminals may all be withdrawn from the front of the board.

The Royal Society.—The annual meeting of the Royal Society was held last week, and was followed by the anniversary dinner, which took place at the Hôtel Métropole. A report of the council for the year now passed discloses that the society has done good work, and it is taking the leading part it ought to do both in scientific matters of the United Kingdom and also in the furtherance of the general science of the world. The first item dealt with in the report is the National Physical Laboratory, which was to have been carried on in the buildings of the Kew Observatory. Owing to the unexpected opposition to the erection of a laboratory in the Old Deer Park, valuable time has been wasted. The council express regret at the decision of the Government in this respect, but they are pleased to accept the site offered to them by her Majesty's Treasury at Bushey House. There some 30 acres of ground will be available. Reference is then made in the report to the committee appointed by the Board of Trade to investigate the interference of electric railways with magnetic observatories. The instruments used in making the observations in order to lay experimental data before this committee were devised by Mr. W. Watson, the assistant professor of physics in the Royal College of Science. The Board of Trade's decision on the matter is awaited with grave anxiety. It is announced in the report that the catalogue of scientific literature of the world will be commenced on Jan. 1, 1901. The contract for the printing and publishing of the same for the International Committee having the matter in hand is made in the name of the Royal Society. Her Majesty's Government has guaranteed £1,000 a year for five years to make good to the Royal Society part of any loss which may be incurred in consequence of this publication. It is hoped, however, that this guarantee will not be called upon. With respect to the bequest of £4,000 under the will of the late Prof. Hughes, the Royal Society has determined to award the income annually as a prize, either in money or in the form of a medal, for original discovery in physical science. The award will be called the Hughes Medal. It will be awarded without distinction as to either sex or nationality. Discoveries connected with electricity and magnetism will have the preference when the award is being considered. It is also announced in the report that the electric lighting installation at the Royal Society's house is being extensively altered to bring it up to modern requirements, and that both the alternating and direct currents will be henceforward available in the building for demonstration purposes. The reconstruction of the installation is being carried out under the guidance of Prof. Ayrton. Lord Lister distributed the prizes for the past year, amongst which, we note, were the Coplin Medal to Prof. Marcellin Berthelot (foreign member) for his brilliant services to chemical science; the Rumford Medal to Prof. Antoine Hewir Becquerel for his discoveries in radiation proceeding from uranium; and a Royal Medal to Major Percy Alexander MacMahon, F.R.S., for the number and range of his contributions to mathematical science. A distinguished number of guests attended the annual dinner.

Wireless Telegraphy.—Some interesting experiments have recently been carried out in Germany by Prof. Braun, of the physical laboratory of the Strasbourg University. The experiments have been made with the object of increasing, if possible, the range to which these wireless telegraphy messages can be dispatched. Up to the present, however, the statements made by the authorities in Berlin do not disclose any claim for distances as great as have been successfully signalled over by Mr. Marconi. The experiments were made between the Brocken (the highest mountain in North Germany) and the Kyffhauser (in Thuringia). The actual distance was about 40 miles, and messages were successfully transmitted and received. Up to the present only untechnical descriptions have been given, from which it is not easy to understand exactly what the arrangements are. It seems, however, that there is a transformer between the discharge circuit of the condenser and the circuit in which the oscillatory currents sending the message are induced. The professor's system is also in use between Cookshaven and Heligoland, a distance of about the same length, and is said to work well. As regards the Marconi system in our own country, it is being boomed quite as much as ever in the daily papers. Without doubt the company has the right to manage its own affairs in the way it likes, but the methods adopted are not those which recommend themselves to scientific men. It may be advisable from their point of view to withhold information from those who are able to judge of the value of the system, but this should not be accompanied by very numerous interviews with the editors of half-penny papers, who draw quite erroneous conclusions. A perusal of the remarks made by the interviewers, as published in several papers during the past week, would lead the untechnical man to conclude that it is only the obstinacy of the Post Office officials which prevents the Marconi system displacing the ordinary systems of telegraphy in the British Islands. Even this faulty conclusion would be harmless were it not for the fact that it may result in the public paying fancy prices for the shares in the Marconi Company. In certain situations the Marconi system of telegraphy is useless, and there has been nothing done up to the present which shows any signs of enabling it to compete with ordinary telegraphy over land lines, or even with submarine cables, unless the conditions are exceptional—as, for instance, when connecting between the mainland and an isolated lighthouse round which a violent sea washes. An example of the telegraph we refer to is one which has just reached us in connection with experiments to be carried on from Southend Pier. We are informed that automatic signals are to be continuously sent from a 30ft. mast erected on the pier, which signals are intended to warn steamships coming into the Thames in a fog of their danger. To give weight to the note, one is told that experts from the Board of Trade, Trinity House, Lloyd's, and other public and private corporations are to witness the trials. The fact remains, however, that although in a fog the signals may be received on board a boat, the occupants of that boat will be unable to know either in what direction the danger is or the distance they are away from the sandbank or rock from which the warning is supposed to issue.

THE ARRANGEMENT OF THE DISTRIBUTING NETWORK.

BY CHAS A. GILLIN.

(Continued from page 766)

Continuance of Supply of Electric Energy.—Supply station engineers generally recognise the necessity of an uninterrupted supply of electric energy, and it is the purpose of this section to consider the points relevant to the subject matter of this article which that question raises. There are two chief causes of interruption in the supply of electricity—viz.: (*a*) the breaking down of generating machinery or steam auxiliaries; (*b*) short-circuits or very bad "earths" on the distributing network.

Of these causes we are only concerned here with the latter, which is undoubtedly the more important for a twofold reason—viz., because it will be by far the most frequent cause of interruption of supply when the cables begin to show signs of deterioration; and, secondly, because of the fact of the cables being out of sight, and very often, therefore, not receiving the attention and care which they otherwise would receive. When a short-circuit or a serious "earth" occurs on any system of mains, it is necessary to localise the fault and disconnect the faulty cables from the main network until the necessary repairs

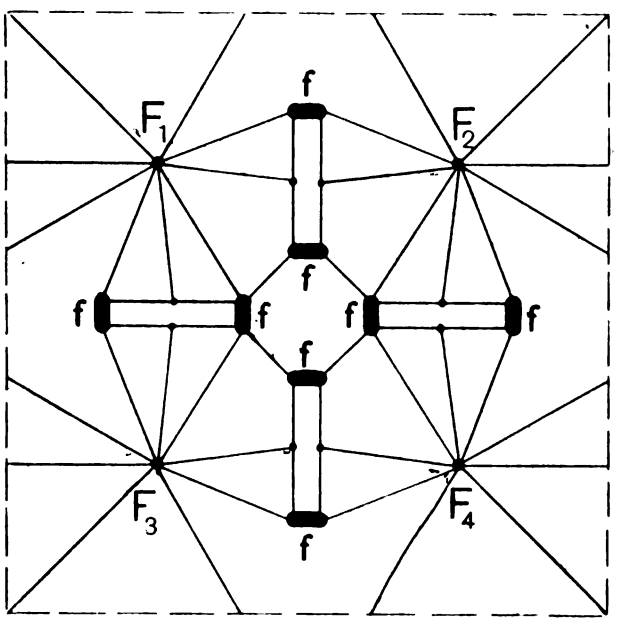

FIG. 4.

have been effected. If the fault is of so serious a nature as to endanger the whole undertaking, its position will perhaps be self-evident; but in any case it will be of the utmost importance to locate it and cut it out without loss of time.

The detailed arrangements for facilitating the localisation of faults are treated of in the following section of this article (Section 4). Our present problem is to design the network so as to reduce to a minimum the number of consumers who would have their supply of electricity cut off in the event of the development of any fault on the system, while at the same time keeping in mind the limitations already laid down in other directions (*vide* Sections 1 and 2). The Board of Trade rules and regulations prescribe that the system of distributing mains must be so arranged that if it becomes necessary to stop the supply of current through any mains for a longer period than one hour, the maximum number of consumers from whose premises the supply is cut off must not exceed 80, and that in no case must the stoppage exceed in amount a maximum power of 200,000 watts.

Fortunately, the plan we have already adopted in Sections 1 and 2 lends itself admirably to the present purpose, for the better interpretation of which reference must be made to Fig. 4, which, it will be observed, is based on Fig. 2. The feeding points are shown, as before, at F_1, F_2, F_3, F_4, and the sections into which the network is divided are indicated by dotted lined squares, while the points at which the different sections are connected to each other are indicated by the letter *f*. In Fig. 4 prominence is given to the points of connection between the several sections of the network, because the first object at which we must aim is to be able to readily isolate any section harbouring a fault, without unduly interfering with the remainder of the distributing system. One method of obtaining this desideratum is to have each individual section connected to all its contiguous ones at a very few points, so that it can be disconnected in a very short space of time. These connections might, with advantage, be made by means of fuses or carefully-adjusted automatic circuit breakers, so that if a heavy rush of current, due to a fault on the system, takes place to any given section, the circuit would be broken at these points, and the section containing the fault completely isolated. The fault may then be easily traced to a short length of cable, and this length being cut out, the whole section remaining can be connected up again.

Probably some difficulty would be experienced in connecting the section to the main network if a reasonable number of consumers had put their switches on. As a matter of fact, if these switches connected continuous-current motors to the distributing mains, it would be a practical impossibility to *directly* reconnect the section to

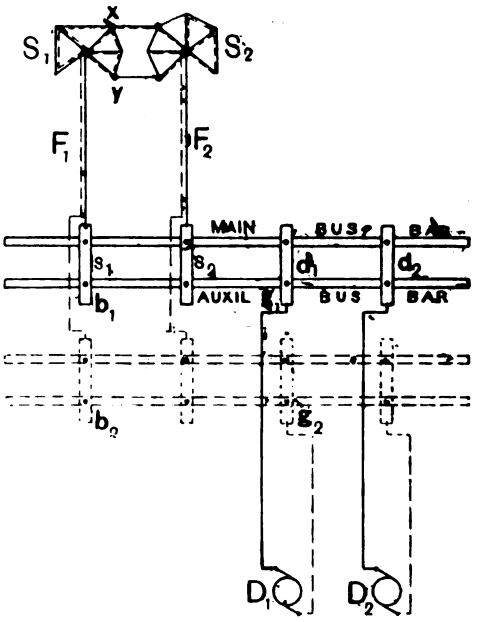

FIG. 5.

the main network, for the armatures of the motors would represent a complete short-circuit across the mains to which they were connected. To safely effect the reconnecting, therefore, the switchboard at the generating station or distributing stations should be arranged so that one or more generators could be used for supplying any individual section of the network; because when, after having been disconnected, any section is again ready for receiving its supply of current, it will be always advisable, if not always necessary, to run a generator on that section from zero voltage, and gradually increase the pressure until the normal voltage is reached before throwing it in parallel with the main network.

The arrangement of the switchboards, etc., is shown diagrammatically in Fig. 5, where D_1 D_2 represent generators connected through their switchboards to the plug-boards d_1 d_2, by means of which they may be connected either to the main 'bus bar or to the auxiliary 'bus bar. S_1, S_2 represent two sections of the distributing network, which are joined through their respective feeders, F_1, F_2, to the plug boards s_1, s_2, by means of which they also can be connected either to the main 'bus bar or to the auxiliary 'bus bar. The dotted lines in the diagram represent the negatives, the full lines representing the positives. If after an interruption in the supply of current S_1 is isolated by being disconnected at *x* and *y*, and it is required to recommence the supply, plugs must be inserted at b_1, b_2, g_1, g_2, and the generator D_1 must be run up gradually to the

Digitized by Google

normal voltage, when S_1 can be easily reconnected at x and y in parallel to the main network. The feeder F_1 can then be again connected to the main 'bus bars, the generator D_1 being also paralleled to the main 'bus bars, or taken off altogether as the circumstances require.

An objection to the employment of fuses for the above-mentioned purpose is that the fuse or fuses joining a section to the main network at any single point may burn out, and the cause thereof may be simultaneously removed, thus leaving the remainder of the fuses joining that section to its neighbouring sections quite intact. This would probably cause a slight difference in pressure in the premises of consumers in close proximity to each other, and consequently give reason for complaint; and as there may be no indication at the station of any of the fuses having burnt out, no steps would be taken to immediately replace them. Possibly, however, some means of indicating the fact may be thought out, and this objection thereby removed.

In the case of employing automatic circuit breakers, it is a very easy matter to arrange to indicate the opening of the circuit breakers by means of pilot wires connected to some signalling arrangement at the station, a bell being rung or a lamp lighted until the circuit breakers are replaced.

It is desirable to have these fuses or circuit breakers in specially-constructed boxes placed above the ground so as to render them more accessible, and their positions more conspicuous. The adoption of the above-described method, whatever its objections, would ensure continuance of supply in at least the larger portion of the network, the details, of course, being modified to suit special requirements.

4. *Facility in the Localisation of Faults.*—With the ageing of the cables the localisation of faults will become a very important item in the working of electricity supply stations, and when the area of distribution increases, and mains are extended into almost every street in the more densely-populated parts of the district, the work of localisation will become correspondingly more difficult. To obtain any great facility in the localisation of faults, the network must be arranged perfectly systematically from the commencement of the undertaking, and all subsequent extensions of mains must be made to comply with this systematism.

Whatever the methods of localisation adopted, it is manifest that the arrangement of the network will play an important part in the time within which the position of a fault will be found, and if that arrangement of the network is effectual for the expeditious localisation of faults by any particular method, it naturally follows that it will be equally effectual for readily locating faults when any other method of localisation is employed. The arrangement which we have previously adopted of dividing the whole network into sections again commends itself to our purpose, for it is possible by means of pilot wires running to various points in the network, and connected to indicators at the generating station, to show, immediately a fault occurs, the section in which it is situated. This method of locating a fault to one particular district is used with great success in Berlin, in addition to the system of fault signalling, generally known as the Berlin system, which in most cases requires a test wire in every cable.

Reference was made in Section 3 to the desirability of having only a very small number of connections between each section and the main network, so as to confine the effects of a breakdown to one section without interfering with the whole network. This will also serve to expedite the work of locating a fault within narrow limits in the event of either of the Berlin systems not being used; for, after isolating all the sections (from each other), that one which is harbouring the fault may easily be found without interrupting the supply of current to any of them, by any one of several well-known methods—such as holding a search coil, connected to a detector or telephone, over the cable feeding the faulty side of the section, while momentarily earthing the other pole of the same feeder; or by noticing which of the current indicators in the feeder circuits is most affected by momentarily earthing the 'bus bar of the opposite polarity to the cable bearing the fault; or finding, by using the pilot wires, at which feeding point the least difference of potential to earth exists while earthing the opposite 'bus bar at the station, etc. By working in this manner a fault can be located to a small district in a very short time without causing any inconvenience through interrupting the supply.

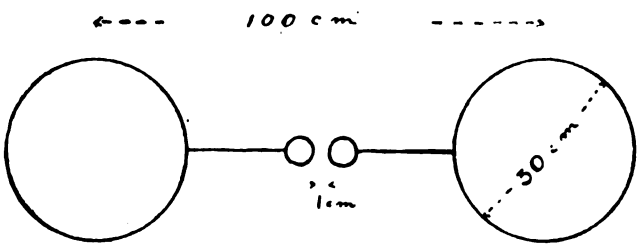
(*To be continued.*)

ELECTRIC OSCILLATIONS.

The second of the four Cantor lectures now being delivered at the Society of Arts by Prof. J. A. Fleming, was given on Tuesday last. To begin with, the lecturer referred to the experiments of the first lecture, and proved that the inductance of a circuit through which these oscillatory currents were passed was due rather to the form of the circuit than the permeability of the materials composing that circuit. He had given in the last lecture the formula by which the frequency of the oscillations set up in the circuit by the discharge of a condenser could be determined. It now became necessary to distinguish between free vibrations and forced vibrations. For instance, an alternating current of high frequency could be sent through a circuit, the natural period of vibration of which was not the same. Mechanical illustrations were given to show that a spring could be forced to vibrate at any period desired, in spite of its natural period being a definite quantity. It was now established that all charge and discharge effects in an electric circuit behaved as if a Leyden jar were being charged and discharged. The exchange of energy which took place was always accompanied by the disappearance of a certain amount of that energy. This was due not so much to the resistance of the circuit as to the electric waves set up in the atmosphere, which dissipated energy. In the elementary case, if a sphere were charged with electricity and placed in an ordinary room, the walls acted as the outer coating of a Leyden jar, of which this sphere was the inner coating. The period of the vibration set up by the discharge of such a charged sphere had been determined by Prof. J. J. Thomson. He found that the period was equal to $\frac{R}{4{,}153 \times 10^6}$, where R equals the radius of the sphere in centimetres. From this formula, in a sphere 32in. in diameter the period of vibration would be 100-millionth of a second. The period of the earth considered in the same way would be one-sixth of a second, while the sun would have a free period of $16\frac{2}{3}$ seconds. It was, however, exceedingly doubtful if the earth was charged and discharged as a whole, and whether it could be considered to act in the same way as a small sphere placed in a large room. In that case the stars might be considered as an outer coating of the Leyden jar. It was very probable that the upper layers of the atmosphere acted as the other coating, and in this case another formula was applicable. This had also been worked out by Prof. J. J. Thomson, who found that, assuming the upper layers of the atmosphere acted as an outer coating, the period in the earth's discharge would be one-eleventh of a second. The amplitude of the vibration would be decreased one-thirty-fifth each vibration. Prof. Fleming proceeded to classify electric circuits into two classes—*i.e.*, good electric radiators and bad electric radiators. Anything in a circuit which tended to dissipate energy, lengthened the time during which oscillations took place. It also followed from this that in order to get a good number of oscillations for each discharge, one had to employ what was a comparatively poor radiator. The next division of the subject taken up was that of the synchronism between different electric circuits. As an example of what could be done with low-frequency alternating currents, the Campbell frequency indicator was exhibited. In this instrument the frequency of the alternating current supplied is ascertained by altering the period of vibration of a steel spring until it moved in synchronism with the alternating-current periods. The well-known interactions which take place with these low-frequency currents between capacity and self-induction were illustrated by the lecturer, who then proceeded to show some

Digitized by Google

experiments on synchronised circuits with high-frequency oscillations. He took the same connections as in the first lecture, in which a small incandescent lamp was lighted in the secondary circuit of a transformer working with oscillatory currents. With about 8in. between the primary and secondary coils of this transformer the small lamp was incandesced. If, however, the secondary coil was moved farther away, the lamp went out. Prof. Fleming then connected in series with the lamp a small condenser which had the correct capacity for making the period of free vibration of the secondary circuit the same as that of the primary circuit. It was then seen that the lamp could be lighted up although the coil was removed to a distance of about 50in. from the primary circuit. In the circuit as used the magnetic force falls off inversely as a cube of the distance from which the wonderful effect of the tuning could be gathered. The incandescent lamp required about half an ampere to incandesce it, and this current passed through the glass of Leyden jar. The next experiment consisted of adding another Leyden jar parallel with the first, which put the circuit out of tune and extinguished the lamp. It was explained in the first lecture that the inductance of the circuit also altered the period of free vibration, and accordingly a coil of wire was introduced into the primary circuit of the oscillatory current transformed. This coil of wire was made on what the lecturer called the accordian principle, as the adjacent layers could be brought together or placed further apart at will. The experiment of adjusting this inductance so that the primary circuit was again tuned to the secondary was successfully accomplished. In order to show how accurate the tuning had to be, an exceedingly small condenser, the plates of which were about the size of a halfpenny stamp stuck on each side of a mica sheet, was connected in parallel with the condensers, and this was quite sufficient to extinguish the lamp. Prof. Fleming said that it was quite possible that expert tuners of electric circuits would rank as professional men with pianoforte tuners in the future. He also hinted that local authorities might succeed in distributing electrical energy through certain blocks of ether, and they would provide their consumers with apparatus tuned to receive the electric oscillations of the frequency which they dispatched. This scheme would not succeed if the Postmaster-General claimed the whole of the ether as his property. In order, however, to get these resonance effects, the oscillations must persist. In other words, a good number of oscillations must take place at each discharge, and the discharges want to be more frequent. The lecturer then gave some calculations made by Hertz as to the energy



which could be dissipated by the Hertzian waves. With a discharge in a circuit of the dimensions given in the illustration the energy available was $\frac{1}{2}\frac{15\,(3{,}600)^2}{2\times 9\times 10^{-11}}=\frac{54}{10^4}$ joules. The loss of energy for the first oscillation worked out at $\frac{24}{10^4}$ joules. In consequence of this, no more than five oscillations were to be expected. The time of vibration was $\frac{1\cdot 6}{10^8}$ seconds, and the rate of doing work 45 h.p. The great problem, however, was how to keep these oscillations going, and this, if solved, might lead to the transmission of energy by means of electric waves. He thought the best possible result up to the present was a period of discharge in which oscillations set up lasted one-tenth of the time taken to charge the condenser. He also considered that 1½cm. was the largest gap over which oscillatory discharges had taken place up to the present. The next experiment consisted in using these oscillatory discharges to light up a vacuum tube at the end of two long parallel wires stretched across the room, and it was shown that there existed one point at which these wires could be short-circuited without extinguishing the tube. This point divided the circuit up into two parts of equal free vibration period. After referring to a theory by which all colour effects could be explained by electro-magnetic resonance, Prof. Fleming went on to describe the success which had attended Mr. Marconi's efforts in the use of tune circuits for wireless telegraphy. Messages between adjacent instruments in signal stations were sent and received without interference and over a distance of 65 miles. The method used could not be disclosed at present, but there was no reason why 20 different messages might not be sent and received at the same time from one point. The two signalling stations between which these experiments were carried out were on opposite sides of a line between the Admiralty stations for experimenting with wireless telegraphy, and it was worthy of note that the signalling on this Admiralty circuit had not been interfered with. It was announced that the next lecture would take place on Monday, the 10th inst.

ON THE SUPERSESSION OF THE STEAM BY THE ELECTRIC LOCOMOTIVE.

BY W. LANGDON, VICE-PRESIDENT.

(Concluded from page 779.)

In his presidential address to the Institute of Mechanical Engineers in 1898, Mr. S. W. Johnson, the locomotive engineer for the Midland Railway, furnished valuable data in relation to the cost of moving railway trains. From this data I, by his courtesy, am enabled to furnish the details shown on Table VI., which shows that the average cost for 24 years for drivers and firemen was £358,635, or 2·650d. per train mile; and that for repairs and renewals, £357,460, or 2·641d. per train mile. To arrive at the cost for drivers and attendants for the electrical locomotive, I might revert to Table IV. and deduce from it, at a given rate of wage per hour, for the number of trains occupying the line for that period, the kilowatt-hour cost, but this, it appears to me, would not be quite right. There can be no question that the cost incurred by the locomotive department is extremely heavy,† but it is a charge incumbent upon the working of the traffic, and whatever are the conditions which militate against a reduction in this charge with the locomotive department, presumably they would hold good against the electric unless the traffic could, under the latter, be so facilitated as to enable it to be got through with greater speed and less shunting. It is not clear this could be done. I am therefore, very reluctantly I must admit, obliged to adopt the extremely heavy cost incurred by the steam locomotive, for there would be very little, if any, difference in the rate of pay to the respective class of men. The repair and renewal of electrical machinery, whether in relation to the generating or the locomotive plant, should be considerably less than that of the steam locomotive plant, for the reason that there will be extremely few moving parts, while many small units, used for pumping and other like purposes, would be provided for from the central generating station at a less cost or entirely abolished. The train mileage (Table IV.) run by the 14 trains during one hour is 479. Assuming that the cost attending the repair and renewal of the electrical machinery will be 2d. per train mile, as against that for the steam locomotive power and works—viz., 2·641—we shall have a result of 0·1916d. per kilowatt-hour. There is yet one more addition to make. The cables and contact rail are peculiar to the electrical system. I do not include them in the above 2d. per train mile for repair and renewal of machinery. Having regard to the value of the recovered material, I assume 2½ per cent. on the primary outlay will meet the renewal of cables, and 4 per cent. that of the contact rail. This means 0·0249d. per kilowatt-hour. Table VII. furnishes all these items, against each of which is also shown the cost per train mile—*i.e.*, the cost per kilowatt-hour multiplied by the total output—viz., 5,000 kw. for the hour's work—divided by the train mileage worked during the hour—viz., 479.

Therefore, if my deductions are correct, it would appear that the cost of working by electricity as against that for the steam locomotive is, per train mile, so far as the Midland is

* Paper read before the Institution of Electrical Engineers, Nov. 29.

† Assuming the weekly wage of driver and fireman to amount to 90s., probably an excessive sum, it would seem that the weekly mileage travelled would be but 407. If the wage were 70s., the mileage would be but 317.

TABLE V.—Estimated Cost of Generation and Distribution of Current.

Details of Charges.		Per annum. £	Per kw.-hour. d.
1. Capital outlay, £470,000—interest at 3½ per cent.		16,450	0·0901
2. Generating station: Salaries and wages—			
1 chief engineer	£500		
1 assistant ditto	250		
3 switchroom attendants, at £150 each	450		
1 clerk	120		
7 engine-room attendants, at 40s. each per week	728		
7 assistant ditto, at 35s. each per week	637		
12 stokers, at 30s. each per week	936		
15 labourers and cleaners, at 22s. each per week	858		
		4,479	0·0245
Coal, at 3·0lb. of coal per kilowatt-hour—58·667 tons, at 7s. 11½d. per ton		23,345	0·1279
Water, at 25lb. per kilowatt-hour, and 2d. per 1,000 gallons		913	0·0050
		28,737	0·1574
3. Sub-stations (5): Salaries and wages—			
5 assistant engineers at £200 each	£1,000		
20 attendants at 40s. each per week	2,080		
20 assistant attendants at 35s. each per week	1 820		
10 cleaners at 22s. each per week	572		
		5 472	0·0299
4. Outdoor service: 5 rail-jointers and fitters at 40s. each per week	520		
Material, etc.	230		
		750	0 0041
5. Oil, waste, and sundries		2,000	0·0109
Total estimated cost of generation and distribution of current		£36,959	0·2023

TABLE VI.—Steam Locomotive Charges.

Average Midland Railway Total Locomotive Expenditure, etc., during 24 years, 1873-96.		Cost per train mile. Pence.
Running Expenditure.		
Wages: Drivers and firemen	£358 635	2·650
Cleaners, coalmen, etc.	94,422	0·698
Water	28,575	0·211
Oil and stores	44,842	0·331
Coal and coke	289,595	2·139
Total running expenditure	£816,069	6·029
Repairs and Renewals.		
Wages	178,718	1·320
Materials	178,742	1·321
Total repairs and renewals	£357,460	2·641
Salaries	24,187	0·179
Turntables and buildings	2,861	0·021
Gas	9,868	0·073
Gross expenditure	£1,222,899	8·943
Tons of coal and coke consumed		727,889
Cost per ton		7s. 11½d.
Train mileage		32 485,530

TABLE VII.—Electrical Charges.—Cost in Pence per Kilowatt-Hour and per Train Mile.

	Per kw.-hour.	Per train mile.
Generating charges	0·1574	1·643
Sub-station charges	0·0299	0·312
Outdoor attendance	0·0041	0·043
Oil, waste, and sundries	0·0109	0·114
Locomotive drivers and assistants (this item is shown at the cost incurred under present mode of working)	0·2538	2 650
Repair and renewal of machinery, motors, etc.	0·1916	2·000
Renewal of cables and contact rail	0·0249	0·259
Total cost for power and haulage	0 6726	7 021
Interest at 3½ per cent. on primary outlay—viz., £470,000	0·6901	0·941

concerned, as 7·021d. to 8·943d., being an apparent saving of 1·922d. per train mile, or £260,155 on the average yearly cost for the 24 years indicated.

A closer comparison of the chief items may help us to learn where and how so large a saving is effected.

Coal stands in Mr. Johnson's data at 727,889 tons, at a cost of £289,595. Based upon the figure adopted by me—viz., 3·0lb. per kilowatt-hour—the tonnage required is 454,145 $\left(\frac{5{,}000 \text{ kw.} \times 3{\cdot}0}{479} = 31{\cdot}315.\ \frac{32{,}485{,}530 \times 31{\cdot}315}{2{,}240} = 454{,}145 \text{ tons}\right)$ and the money £180,712 $\left(\frac{{\cdot}1279\text{d.} \times 5{,}000 \text{ kw.}}{479} = 1{\cdot}335073\text{d. per T.M.}\right.$ 32,485,530 T.M. × 1·335d. = £180,711). The steam locomotive consumes on the average 50·191lb. of coal per train mile. My figures place the quantity required for electrical energy at $\frac{(5{,}000 \times 3{\cdot}0)}{479}$ 31·315lb. The saving under this head is, therefore, 273,744 tons, which at 7s. 11½d. will account for £108,927. We have to bear in mind that the calculation on which the cost of electricity is based makes no provision for shunting operations. It is based entirely upon the train mileage run. Shunting work is, of course, included in Mr. Johnson's figures, and will account, to some extent, for the difference. The main gain, however, is to be found in the economy of a stationary as against an itinerant generator, as well as in the fact that much coal is consumed by goods and mineral trains when shunted, and by all trains when standing at stations, the whole of which would be saved if worked by electricity. With stationary engines, a less expensive coal than that used for locomotives would be available, thereby effecting a reduction probably more than sufficient to meet the cost for shunting previously alluded to. It may be pointed out that coal is more costly at present. Such is the case, and were my calculations based upon the present rate of coal, the result would largely enhance the advantage of electricity. Say, for instance, that coal stood at 10s. instead of 7s. 11½d., the locomotive cost would be 727,889 tons at 10s. = £363,944, instead of £289,595; that for electricity would be 454,145 tons at 10s. = £227,072, instead of £180,701. The result would be that electricity would show, under coal at 10s. a ton, a saving of £136,872 instead of £108,927, on precisely the same mileage, with a proportionate increased saving at prices ranging above that figure. The fact that dear coal enhances the comparative value of an electrical system—especially with the possibility of coal at a higher rate than 7s. 11½d.—cannot be too strongly emphasised.

Water.—The steam locomotive calls for £28,573, or 0·211d. per train mile; electricity, £7,066, or ·0522d. per train mile—a difference in favour of the latter of £11,507. It is difficult to attempt a comparison between the cost of a largely-scattered supply—water pillars at numerous stations—and a concentrated one—one to every 50 miles or so of line. The site for such a generating station would naturally be selected with a view to cheap water supply, and, as a rule, no great difficulty would attend its selection. A further point to be borne in mind is that, naturally, all machinery would be of the most modern and economical type, and that the working would reach the highest ideal for an electrical plant—viz., an actually constant and perpetual demand.

Drivers.—It is quite clear that whatever may be the cause of the existing heavy charges, it will apply equally to electric as to steam locomotives. The engine must stand by its train, and the men along with it. Any reduction that may be effected will be in the mode of dealing with the traffic. The present condition—viz., that of a mixed traffic travelling at various rates of speed, one class of train being required to make room for another of a more important character—is not destined to effect economy in this branch of expense.

Repair and Renewal.—I have assumed that the cost of repair and renewal would be practically one-fifth less with electricity than steam. I think I am more than justified in this. The wear and tear of stationary engines or motors cannot possibly be so great as that of the steam locomotive. The number of electric locomotives would necessarily be as great, but their wearing parts would be immensely less than those of the latter. Many local units would be entirely dispensed with.

Oil and Stores.—These form a somewhat large item in the running expenses of the steam locomotive. Much of this is for the lubrication of moving parts which would be non-existent in electric engines. Moreover, with stationary engines it is possible to recover, and again use, a great portion of the lubricator employed. It would appear that considerable economies in oil should accompany the employment of electricity.

We may now perhaps glance at possible economies on that which is indispensable for the steam locomotive, but which is unnecessary, or not so largely necessary, with electricity. Water-pillars, turntables, engine-sheds, coal stages—all these are expensive items which with electricity are either not required or capable of considerable modification. Water-pillars, supplemented in many instances by fixed engine power for pumping the water into reserve tanks, involving power-houses, sheds, and other structures, form part of all large stations and many other points at which the locomotive requires to take water. With electricity, water to any extent would be required only at that point at which the central generating station is placed. If this station served 50 miles of railway, then it would take the place of all the pumping plants, water-pillars, etc., otherwise required throughout that section for the steam locomotive. Every pumping station involves the

Digitized by Google

provision of labour, fuel, etc. All water-pillars require special attention during hard weather. Economies in first outlay and annual charges on this account should accompany the use of electricity. Turntables would be unnecessary. The annual outlay for repairs in this respect is not great, but the cost of laying down the large turntables now required is very heavy. As the number of locomotives increase, so increases the demand for engine-sheds. Electric locomotives would of course need housing as well as the steam locomotive, but the space which they would occupy would probably be about half that now required. Wherever we find an engine-shed, there we see an area of land covered with coal; lines of rails applicable thereto; coal stages to which the coal has to be carried, and from which it has to be distributed to the locomotives. First the coal has to be stacked, then loaded into trucks and carried to the coal stage, and thence weighed and placed on the engine's tender. This is the course of procedure at each engine depôt. If we compare it with the work of a large central station, such as that sketched out in this paper, I think it will come home to us that although the work would be large, it could not be nearly so large as at present. If stacking were at all necessary there would be the less quantity to stack, and it would all be dealt with in a more concrete form and at comparatively few centres. Again, in this respect there is reason to look for economies in land, in buildings, and labour. All these are assets directly due to the employment of electricity. Others, not considered in the figures which I have advanced, would, with its presence, be available: the lighting of the trains, stations, goods warehouses and yards, marshalling grounds, etc.; signalling, to some extent, might become automatic; while at large centres where signal boxes have become both numerous and cumbrous, it would appear but reasonable that, with the aid of such a power, points and signals might not only be actuated, but the means for operating them might be so condensed as to admit of the entire duties being embraced within such a space as would enable one man to deal with them. Labour and space would be economised, and less time would be occupied in giving effect to the various operations than is possible with the existing means. To this we may add that obviously it would also provide for the operation of lifts, and other local demands for power which at present have to be met by isolated plants.

Let us now turn to what may perhaps be regarded as difficulties to be encountered. The first question that will arise will be: Are we safe in placing so many of our eggs in one basket? With the steam locomotive we have a travelling unit which has to manipulate its own load, and is in no way responsible for the duties of others. If it breaks down, the inconvenience is chiefly confined to the vehicles it is hauling, and in due course they are extricated from their difficulty by the aid of another engine. With electricity we are locating our power at one spot in so many miles of line, and if that breaks down that section of line is practically dead. But with the usual spare parts—the duplication, if necessary, of the generating units—there should be no reason to anticipate such a failure. The same argument in a measure applies to the power at the distributing stations. Here, however, the case may be met not only by duplication, but by, in emergency, connecting one section through to its neighbour. For the time being inconvenience would be felt; speed would be reduced, but traffic would not be stopped. Of all this we have evidence in that which has already been done. We see railways being worked, tramways operated, and other large undertakings all dependent upon one large and central source for their life and being. Electric railways have become an accomplished fact, and we may turn to those that are in use as exponents of success or of difficulties to be encountered. Does the magnitude of the question we are considering—the eventual supersession of the steam by the electric locomotive—remove it from the category of that which has so far been done? I think not. The basis is there. It is to-day in useful operation. Improvements will come. The mode of working which we see to-day may, and probably will, be simplified, but this will only strengthen that which has already been accomplished. Still, there are points of great interest for consideration. As a rule, that which has been done has, with one or two exceptions, been confined to underground lines, and these exceptions have not, as a rule, dealt with such heavy work as the large overland railways require to compass. Overground railways have to work through all kinds of weather—rain, snow, fog—and at times to pass over rails submerged in water. Winter floods are not unusual in certain localities of nearly all overland railways. These are conditions which will effect the construction of the locomotive, the arrangement of the current collector, and the contact rail, and are subjects for thought not only in themselves but in relation to the mass of undergear which now appertains to all passenger railway stock, as also to the relative position and construction of roads, their repair, and renewal. A question may here intervene whether a similar economy would attend the operation of small branch lines of railway where the trains are few and far between. Consider! Why are the trains so few and far between? The traffic is, we will say, a fixed quantity. There are only so many tons of goods and so many passengers passing over it daily. The steam locomotive is available only at certain times, and to attain economy it is necessary that so many trips only should be made. The accommodation is limited to this. But if the power for working the trains were constant, although reduced, any number of trips might be made. The additional cost would be that only of the driver, for the rest the branch would be no more costly, while the frequency of the communication would tend towards the development of the district, and the consequent increase of trade.

I have now, I believe, fairly set forth the salient features of this question. The data which I have produced speak greatly in favour of electrical energy as a motive power for the movement of railway trains. The economies which it would apparently effect are, indeed, so large as to raise a doubt whether my deductions—whether the figures I have adopted—are fair and reasonable. It must not be forgotten that my calculations are based upon a mileage run clear of stoppages or other contingencies. Stoppages are unavoidable. They *will* arise, and provision must be made to meet them. But I find it difficult to identify them further than I have already done. Stoppages will not affect the coal bill. I have taken the present cost of drivers and firemen to apply to that for drivers and assistants for electric locomotives. My allowance for repair and renewal of machinery will, I think, be generally supported. Necessarily the subject has to some extent had to be dealt with more in the abstract than in detail, but I venture to hope my figures will not be found illiberal. We must not lose sight of the fact that the conditions are a constant load and continuous output for every hour of the year. I believe the cost of shunting at stations and in goods yards may be met by the economy attending the use of a cheaper coal than that which is necessary for the steam locomotive; but assuming that some provision should be made for this, for administration and contingencies, I conclude that 20 per cent. (say £50,000) of the accredited saving will cover it. We thus bring the net annual advantage to approximately £208,124, and if we deduct interest on the primary outlay it will further reduce it to £191,674. Whether it is, in face of the savings to be effected in engine-sheds, coal stages, water-cranes, etc., fair to make a debit in full of this amount, I must leave those who are interested in the question to determine. Broadly, it appears to me to mean this: that were a new company to start with electricity as their motive power, they would not need to take into consideration the interest on the entire additional outlay, because they would save a great portion of it in other directions. But were an established company to adopt it, they would already have incurred the cost for the lands, buildings, etc., and the expense for establishing electric working would unavoidably prove to them, for some years, an addition to their capital charges. Although I feel that my reason for pursuing such a course will be obvious, it may be desirable that I should emphasise the fact that my sole object in availing myself of the data afforded by Mr. Johnson's presidential address to the members of the Institution of Mechanical Engineers is that I might deal with data extending over a long period of years, rather than draw a comparison with a period which might be regarded as possessing some abnormal feature. It must, however, be noted that recent figures tend to greatly magnify the result. I have shown that, with electrical working, certain economies are to be anticipated. The annual amount of these economies is based upon the ascertained saving *per train mile*, multiplied by the average annual mileage for the 24 years—viz., 32,485,580. The mileage for 1899 is 45,453,438, and the expenditure £2,006,069, as against the 24 years' average £1,122,899; and the train-mile cost has risen to 10·59d. as against 8·943d. Assuming that the saving per train mile remained the same—it would probably be larger, consequent upon the increased cost of coal—the resultant saving would be, independent of any deductions for interest or contingencies, £364,006. Large as is the apparent economy thus presented, it would, were it possible to employ a gas plant for so large an output, be increased by the use of the "Mond" gas system. Such a system would appear to invite consideration, at all events for smaller installations, as, for instance, for the operation of branch lines.

Here it may perhaps be asked: What good can attend the production of these figures or the results they advocate, seeing that the railway system generally is wedded to the steam locomotive? Is it probable that any railway company will cast on one side their present equipment for the purpose of taking up that which, although holding out fair hopes of a large economy, is yet in a measure, or in the large measure to which it would have to be applied, mainly an untried agent? To this I reply: Railway companies are under the direction of business men—men who know the value of money. Satisfy them that economies are to be effected—and do not let us forget that the economies are not confined solely to those with which this paper has dealt, but probably to many others indirectly associated therewith, and that the economy embraces a reliable means of working—and they will not be found undesirous of testing its worth.

Digitized by Google

The life of a steam locomotive is not an indefinite quantity. Its replacement by one of more modern construction or of greater power, quite apart from its ultimate destruction by wear and tear, is an appreciable fact. As traffic increases, so additions have to be made. We see so many new engines ordered year by year. What is to prevent a railway company, instead of thus perpetuating its annual costs, setting apart portion by portion of their system for operation by electrical energy, and, instead of ordering for, say, that portion of their system, steam, to order electric locomotives; and thus to bring, piece by piece, their entire system under electrical operation? No sane railway management would do otherwise; and I assume that, should my figures stand unrefuted, no railway company would desire to follow any other course. Prove its economy, prove its reliability, and there is nothing in the fact that railways are, for the time being, the slave of the steam locomotive, to militate against their supersession by electrical energy.

That this paper deals with a problem which, sooner or later, will force itself upon the attention of all who are interested in railway progress, few will be disposed to dispute. So far it has been considered solely in the realm of economical working—in the interest of the railway shareholder. But are we justified in looking at it only from this standpoint? Does it not embrace a question of still greater magnitude? Is it not one of even national interest? If, by the aid of electricity, we can save no less than 18·876lb. of coal per train mile, it is clear we could save *no less than three million tons* a year (396,241,265 train miles ×18·876lb. =3,339,040 tons) if all our railways were worked by that agency. View it again from still another standpoint. Twenty thousand locomotives moving about throughout the land cannot fail to leave their mark behind them. Our railway stations, the telegraphs which traverse the railway routes, the trees which grow on its borders, all bear evidence of their presence. The supersession of the steam locomotive by the electric locomotive will bring with it a purer and a more cleanly atmosphere—cleanly railway stations, cleanly railway carriages, a higher and a purer sanitary condition of life.

Discussion.

Dr. John Perry, from the chair, said that there were a number of locomotive superintendents present, who, he hoped, would speak on the subject before them, but that he proposed to call upon Mr. Mark Robinson to open the discussion.

Mr. Mark Robinson complimented the Institution on the most interesting and valuable paper read by Mr. Langdon. The matters raised in it were of the utmost importance to the country, and particularly to the industrial sections of the community. Also he considered the author's conclusions the more valuable because he had taken such an impartial and moderate view of the problems involved in the conversion of railways to electric driving. He proposed to discuss particularly one detail of the proposed scheme for equipping the section of railway between London and Bedford. Thus Mr. Langdon suggested one large station with 10,000 kw. of plant in it, and five sub-stations along the route. No doubt this arrangement had been carefully considered, but he would raise the question as to whether this large station would really be more economical than five stations each containing 2,000 kw. of plant placed where sub stations are indicated in the diagram. In the large station, with its 16,000 h.p. of plant, there would probably be four engines, each of 4,000 h.p. There was considerable doubt in his mind as to whether the extra economy gained by the use of such large engines would make up for the losses in the transmission lines and in the transforming apparatus at the sub-station. There was an economy gained from increasing the size of the engines, and this had been largely taken advantage of in America. They had, however, used slow-speed engines, in which the advantage from the larger size was more than with high-speed engines. This was because the ratio of the volume of steam to the surfaces exposed to radiation was greater the larger the engine was made. It had been proved by the late Mr. Willans that with high-speed engines this hardly applied, and one of the advantages of the increased speed was that good economies could be obtained with small-sized engines. Thus it was only a 40-h.p. engine on which Mr. Willans made his historical experiments, and on which he obtained a steam consumption as low as 12½lb. per indicated horse-power. If his suggestion were adopted of placing the plant in the sub stations, three engines of 800 h.p. each or four of 700 h.p. each might be used. He thought that the first cost would not be as much as with the high-tension feeders, and the transforming gear would be saved. There would also be rather a larger factor of safety by providing a generating station for each section. When working, the loss given by the author as 17 per cent. in the high-tension line and transformers and 10 per cent. in the rotary converters would be saved. In consequence of this, they would also be able to reduce the capacity of the generating plant by about 22 per cent. He estimated that the first cost could be decreased from £470,000 to £273,000. He would finally state that while for metropolitan lines a high-tension system of transmitting power from a station in the suburbs might be the right thing, he did not think it was in the country, where additional advantages with respect to cheap sites for works could be obtained. He concurred with the author in his statement of the advantage to be derived from placing motors on trains and keeping the steam plant in stations.

Mr. G. C. Cuningham, of the Central London Railway, also complimented the author on his paper. The real question was the consumption of coal per ton-mile with electric driving as compared with the quantity taken by the locomotive. Some years ago he was connected with the Southern Canadian Railway, which ran through an exceedingly level country, and was almost free from curves—in fact, it represented the best possible condition for low coal consumption. He found that it took on the average ·4lb. of coal per ton-mile on goods trains, and 0·8lb. on passenger trains. On the Liverpool Overhead Railway, which was also practically level, the average was about ·4lb. of coal per ton mile. On the Central London, after deducting for the power required for lifts and for lighting the generating works, he found that they required about ·5lb. of coal per ton-mile. The energy also came out at 70 watt-hours per ton-mile,* whereas on the Montreal electric tramway system, where the grades were very heavy, no less than 300 watt-hours were required per ton-mile. In Montreal they did not succeed in reducing the coal consumption to less than 3·6lb. per kilowatt-hour, while the total cost of generation and distribution, excluding interest and capital charges, came out at about ¼d. per unit. Everything depended on having an economical power-house on a site where water was abundant.

The Hon. C. A. Parsons said he had carefully checked Mr. Langdon's figures, and considered them liberal; 3lb. of coal would be quite sufficient to allow per unit. With respect to the size of the generating station, this largely depended upon the facilities on various parts of the line for such a station where coal and water were abundant. The one advantage of the high pressure distribution was that the best position could be selected, and he thought that the consideration of the artisans' dwellings available should not be neglected. Another most important point in favour of the electric line was that the traffic on country sections could be improved by running smaller trains at more frequent intervals without extra cost.

Mr. H. A. Hoy, of the Lancashire and Yorkshire Railway, said that a study of the subject had led him to fall in with the views expressed by Mr. Robinson in favour of smaller generating units. He thought the dynamo should be constructed to give the 600 volts required for the line. While not going so far as had been tried by Mr. Heilmann in France, he thought that when the railways were converted to electric working it might be convenient to have a generating plant which could be transferred to that section on which excessive demand arose for limited periods. He had recently seen the third-rail line near Hartford, in America, in which the voltage required for the third rail was generated direct, and he gathered from the engineers of that line that they proposed in equipping extensions to provide additional generating works along the line of route on the same system.

Mr. J. S. Raworth commented on the most valuable papers on varied subjects which Mr. Langdon had from time to time contributed to the Institution's *Proceedings*. Their value was increased by the impartiality of their author. He proceeded to divide the most prolific readers of papers other than Mr. Langdon's into two classes. One was represented by the man who hoped by so doing to hasten the universal use of high-speed engines, while the other was the professor who was so charged with information that he must read papers or burst. He would remind the meeting that the main issue was that they should convince the financial element in railway companies—*i.e.*, the shareholders and directors—that electric locomotives would save them money. These people did not mind at all about the systems, but wanted to be assured of the financial results. He did not quite follow Mr. Langdon's way of arriving at the power required for the St. Pancras to Bedford section of line, but he had gone through calculations on his own account as to the foot-pounds required, and with 16 trains he found that 9,850 kw. of generating plant were needed. Mr. Langdon's comparison of the coal and wages on the steam lines for the last 24 years, and for that required for electrical working, was in favour of the steam locomotive, as the coal assumption per train mile had gone up very much of recent years. He also considered that the author should not have taken the 3½ per cent. interest on the cost of conversion into his calculations, as the figures for the steam locomotives included no such charge.

Mr. Henry Maver asked, on behalf of the Glasgow local section, that the discussion of Mr. Langdon's paper should be kept open until the 12th inst., in order that that section might take part in the discussion.

Colonel R. E. B. Crompton much regretted that he would be unable to be present at the next meeting, as he would like to have gone more into detail than he was then able to do. He had had to work out for the Government of India particulars for an electric line across the Himalayas. In the course of calculations for the same he had to make assumptions as to the traffic on the line, whereas Mr. Langdon had actual figures to go by. The first thing that he (Mr. Crompton) was struck with was the great discrepancy between the actual horse-power required on the line and the full horse-power of the locomotives—in other words, the load factor was so bad. This low load factor was, he thought, the explanation why the question was still raised by locomotive engineers as to the advantages of compound locomotives. This discrepancy between the horse power required and the horse-power of the locomotives disappeared as soon as the power was taken from a number of fixed stations, as in an electrically equipped line. On the question of wages, Mr. Langdon stated that good drivers must be obtained, and hence they should be paid the same wages on electric locomotives as at present. He knew that highly-trained men were required, but the training required for driving

* This is equal to 7·15lb. of coal per Board of Trade unit.—Ed. *E. E.*

Digitized by Google

electric locomotives was not to be compared with that required for working steam locomotives. Without the most highly-trained drivers a steam locomotive could not be got to give its full power or speed, and even then it was apparent that the limits of power with steam locomotives had practically been reached. With an electric locomotive, on the other hand, there was ample margin, and he thought a great saving could be effected in the wages account. Again, on the question of repairs, he thought this item for the electric locomotive would not be anything like so great as with the steam. With the electric motors, only circular bearings, which could be rendered dust-proof, were required. On the other hand, in a steam locomotive the maintenance of sliding surfaces in spite of the grit was difficult. He had, in Africa, had recent experience of this, and it was distressing to see the condition into which these flat surfaces got in consequence of grit. Again, the cost of keeping locomotive boilers in repair was high, and, as hinted previously, the limit of power for locomotive boilers with the present gauge of rails had practically been reached. In fact, engineers had already had to reduce the size of driving wheels in order to get larger boilers. There was no limit to the power which could be generated on the train by electricity, especially if motors were placed on the carriages.

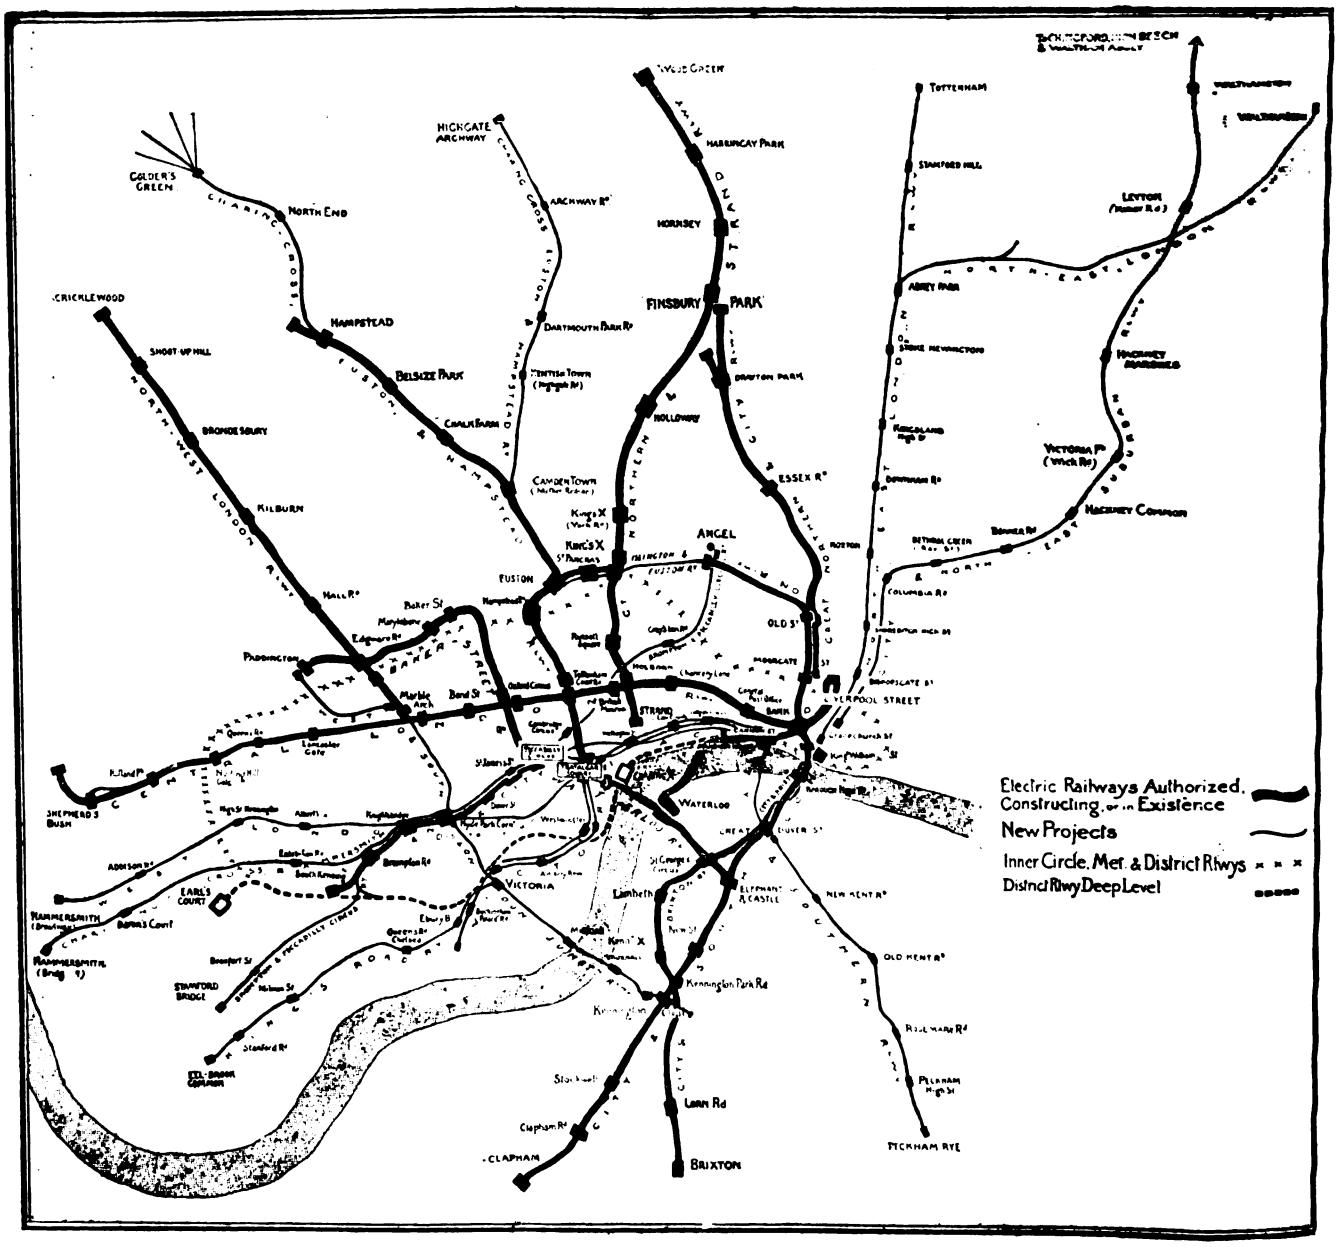
PROJECTED LONDON RAILWAYS.

The accompanying map, which we have ventured to reproduce from the *Daily News*, shows at a glance the respective routes taken by the electric railways authorised, constructing, or projected in and around the Metropolis. The same authority tabulates and comments upon these several schemes as follows.

Old Schemes, Constructing or Authorised.	Miles
Baker-street and Waterloo	5
Brompton and Piccadilly-circus	2
Charing Cross, Euston, and Hampstead	5
City and Brixton	3½
City and South London (Moorgate-street to Angel extension)	2
District Railway Deep Level: Mansion House to Earl's Court	4½
Great Northern and City	3½
Great Northern and Strand	5
	30½

New Projects and Extensions of Railways already Authorised.	
Brompton and Piccadilly-circus	4
Central London (extension to Liverpool-street and loop lines)	1
Charing Cross, Euston, and Hampstead extensions	5
Hammersmith and District	5
City and North-East Suburban	17
City and West End	6½
Islington and Euston	1½
King's-road	2½
North East London	11
Piccadilly and City	2
Victoria, City, and Southern	7
West and South London Junction	4½
	97½

Basing the cost of construction and equipment upon the cost of the Central London Railway, which worked out at £600,000 per mile, we have here revealed by a simple sum in addition a capital sum of not less than £58,540,000 sterling proposed to be sunk in these enterprises. Add to this figure a further million for the electrical conversion of the Inner Circle inferno, and we get a total of £59,540,000.



The Projected London Railways.

Brief consideration of the map enables us to determine

Digitized by Google

for ourselves what justification there is for the adverse comments which have been made with regard to the projected schemes. It has been contended that the new schemes are being promoted without the slightest regard for the needs of London as a whole, and with no fixed idea of interchange of traffic or thought for the general welfare. A glance at the map is all that is needed to drive home the truth of this terse criticism. The total absence of any system in the schemes, taken as a whole, is at once apparent. It may be said that the several schemes are not even calculated to serve their mutual interests. We are threatened with a multiplication of lines, commencing nowhere particularly and terminating nowhere particularly, without any attempt at intercommunication or access from a common terminus. The result, if all the proposed schemes were carried out as they stand, would be to make the present confusion more confounded, an eventuality which would go a long way toward destroying public faith in private enterprise, so far at least as the long needed improved means of local transit are concerned. The best solution of the matter would seem to be two series of deep-level lines radiating from, say, the Bank and Oxford Circus, where common terminii for interchange of traffic should be constructed.

POLYPHASE ELECTRIC TRACTION.*

BY PROF. C. A. CARUS-WILSON.

PART I.—THE POLYPHASE SYSTEM.

The factors which determine where electricity may be substituted for steam on existing railways with the greatest advantage are too numerous to permit of adequate discussion in a single paper. The author therefore proposes to draw attention to some features of the polyphase system bearing on this question, particularly those relating to punctuality and frequency of train service. With steam traction it is necessary to make up trains of considerable length in order to meet expenses, hence where the traffic is small the train interval is large. This is felt most on cross-country lines, where the long intervals between trains is generally a cause of much inconvenience, not only on account of the poor service it affords between adjacent towns, but also because of the great difficulty of making connections at main-line stations. With electric traction, on the other hand, experience has shown that single independent motorcars, carrying, say, 40 passengers, can be run economically at frequent intervals, so that a line which when worked by steam has, say, a train interval of two hours, when worked by electricity might have trains every half hour. If the principal cross-country lines, by which stations on the different main lines are linked together, were equipped electrically, they could be provided with a train service many-fold more frequent than at present obtains, and greatly increased travelling facilities could be offered to the public.

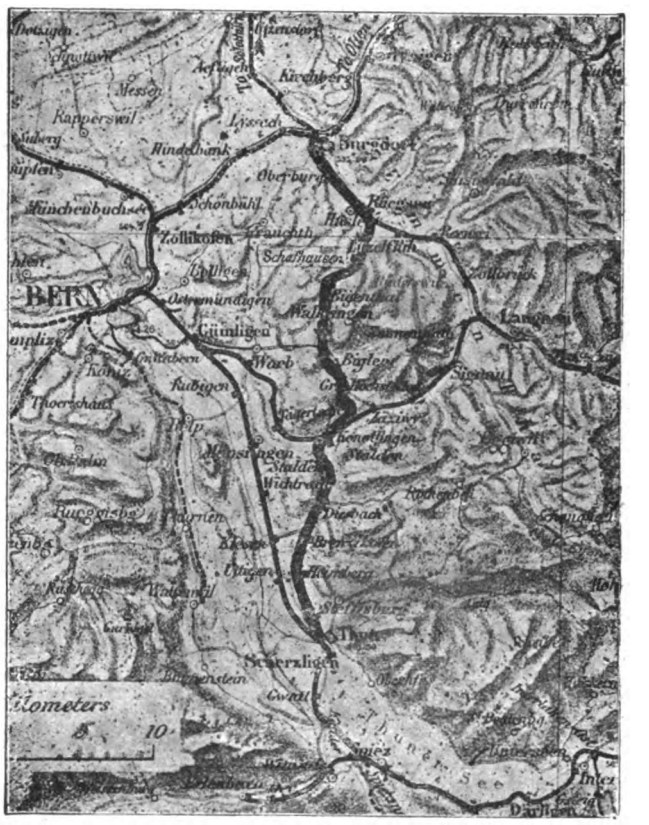


FIG. 1.

The breaking up of the traffic into small units, rendered possible by the substitution of electricity for steam, besides greatly facilitating cross-country travel, would have a marked influence on the punctuality of the train service. The more continuous and uniform movement of the traffic would enable the employés of the line to be more uniformly occupied. The infrequent arrival of long trains with large numbers of passengers and corresponding quantities of luggage would give place to more frequent arrivals of single cars, thus enabling the existing staff to handle the traffic with greater promptitude and facility. The more frequent

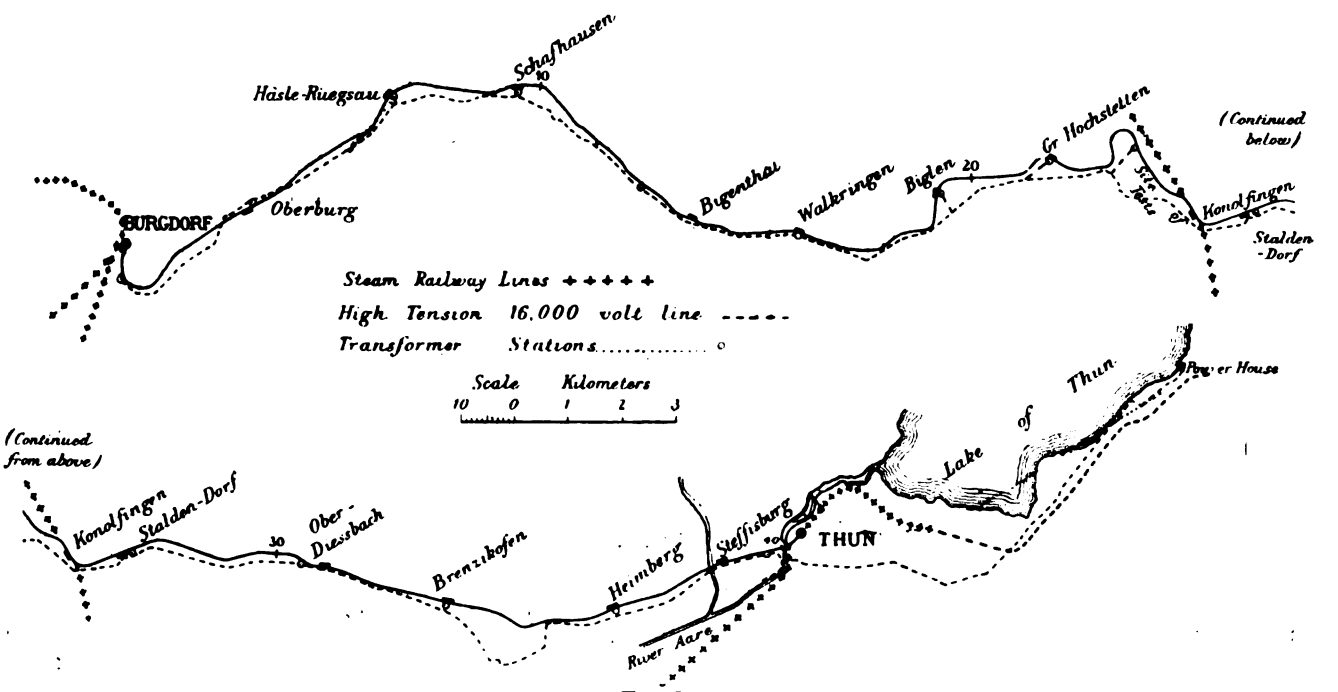

FIG. 2.

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

service would thus be a more punctual service, since the strain on the staff in keeping the trains running to time would be more evenly distributed over the hours of the day, and the work involved in getting each train off diminished in proportion as the train interval is reduced. The advantage of the new system would be most apparent when temporary increases in the traffic had to be handled, as it is on such occasions that the staff is most severely taxed, and the consequent unpunctuality most noticeable. The punctuality of a steam railway is affected not only by the difficulty of handling temporary increases in the traffic at the stations, but also by the influence of such increase on the actual running speed of the trains, particularly on

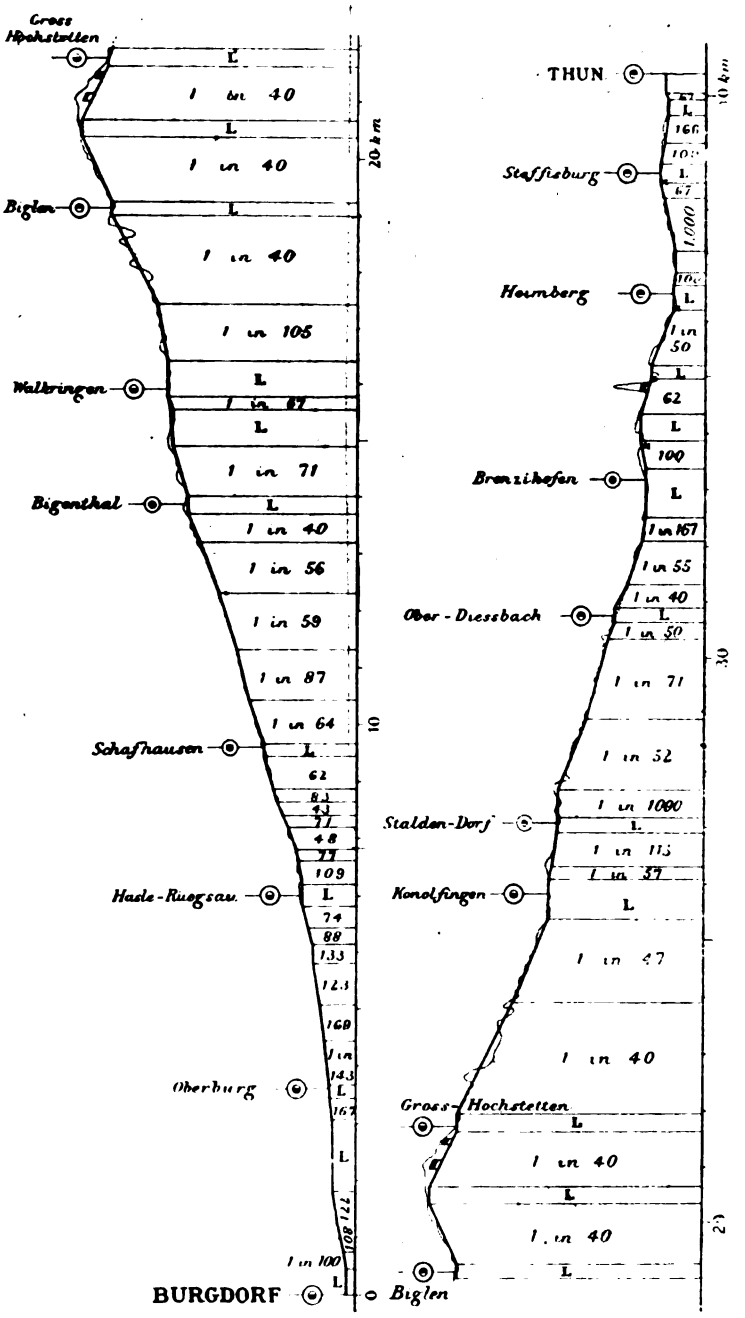

FIG.

lines where the grades are at all considerable. The same difficulties have to be met in an electric railway, and the problem of maintaining a uniform speed under varying load thus becomes one of great importance.

The continuous-current motor, as generally used for electric railway work, shows a large reduction in speed at heavy loads. Thus, in Fig. 28, it is seen that when running light with a 16-ton car the speed is 24 miles per hour, and when hauling seven 16-ton trailers the speed is 15 miles per hour. Hence it has become the practice on electric railways to meet temporary increases in the traffic by adding motorcars each capable of handling its own load. Thus on the South Side Elevated Railway, Chicago, the trains are made up of motorcars weighing 19 tons, each driven by two 52-h.p. motors, the number of cars depending on the traffic, and varying from time to time during the day. The expense of working the separate motors on each car may be reduced by devices such as Mr. Sprague's multiple-unit system, by which one motorman controls all the motors in a train by a single controller. Such systems, however, involve complications in the controlling arrangements, and large first cost in providing each car with a complete motor equipment. In the alternating-current polyphase system the motors run at a practically uniform speed entirely independent of load or grade. Figs. 27 and 28 contrast the action of continuous-current and polyphase motors under conditions of varying loads and grades. Thus a railway equipped with polyphase motors can carry a temporary increase of traffic without influencing in any appreciable degree the scheduled speed, the only exception to this statement being that an increase of load affects the time of starting; this will be considered later on. Experiments have been made, of which records will be given subsequently, showing no appreciable variation of speed when the load on a motor-car was increased from 32 to 68 tons, and 2 per cent. fall when a 50-ton train ran from a level up a grade of 1 in 40. Hence with the polyphase system a temporary increase in the traffic can be carried by adding trailers to the motorcars up to the full power of the motors, with no complication of controllers or increase in the working staff,

Digitized by Google

and without any appreciable influence on the speed. The Burgdorf-Thun Railway in Switzerland is a cross-country line worked on this system, and presents so many features of interest illustrating the points which have here been raised that the author proposes to describe it in some detail.

The Burgdorf-Thun Railway.—This line links together three of the main lines radiating from Berne—namely, those to Olten, to Lucerne, and to Interlaken (see Fig. 1). The first of these is met at Burgdorf, the second at Konolfingen, and the third at Thun. From Burgdorf to Hasle the line runs side by side with the main line to Olten. At Burgdorf connection is also made with Solothurn. The distance from Burgdorf to Konolfingen is 16 miles, and from Konolfingen to Thun is nine miles, making the whole line 25 miles in length. The line is of normal gauge, and carries the ordinary rolling-stock of the other Swiss railways to which it is connected. It is worked entirely by electricity on the polyphase system, the power-house being situated at Spiez at a distance of five miles from Thun. A plan of the line is given in Fig. 2, and a profile in Fig. 3. The train service is shown by the time schedule, which is given in Fig. 5. From Burgdorf to Thun there are 11 trains daily, and 12 from Thun to Burgdorf. From Thun to Konolfingen there are 15 trains daily, and 14 from Konolfingen to Thun. Each train generally consists of one motorcar and one trailer, together capable of seating about 100 passengers. Some of the above-mentioned trains are supplementary trains, running at about 10 minutes headway; these are shown in the time scheduled by dotted lines.

The Electrical Connections.—These are represented diagrammatically in Fig. 25. The generators in the power-house at Spiez generate current at 4,000 volts, which is transformed to 16,000 volts in the step-up transformers. The current is carried at this tension from the power-house along three overhead copper wires of 5mm. diameter to the step-down transformers situated at intervals of two miles along the line between Thun and Burgdorf (Fig. 2). The current is here transformed down from 16,000 volts to 750 volts, and carried from thence to the two hard copper trolley wires, 8mm. diameter, and to the rails forming the third wire. From the trolley wires two sliding contacts convey the current to the stator of the motors, the third connection being through the wheels of the carriages. The rotors of the motors are provided with rheostats and sliding contacts for purposes of control.

The Passenger Motorcars.—A general view of one of these cars is given in Fig. 11. Details of the construction are shown in Figs. 13, 14, and 15. The main frame is 49ft. long and 6ft. 6½in. wide. The distance between the centre line of the bogies is 31ft. The wheel base is 7ft. 2½in. The car, when completely equipped, weighs 32 tons empty, and has seating capacity for 66 passengers. Each bogie is provided with two motors, geared to the driving axles of the car. A general view of one of the bogies is given in Fig. 12, and details of the method of suspending the motors in Figs. 16, 17, 18. There are 83 teeth in the spur wheel, and 28 in the pinion, giving a gear ratio of 2·96. The diameter of the driving wheel is 40$\frac{5}{32}$in. when new. The trailers used are of lighter construction than the motorcars, and weigh 12 tons. Each motorcar is fitted with one of Messrs. Peyer and Favarger's tachygraphs for recording automatically the speed of the car.

The Motors.—These are of the three-phase type, with eight poles, and designed to give 64 b.h.p. each when connected to a line having a tension of 750 volts and a frequency of 40. The speed of synchronism of the motor is 600 revolutions per minute, making the speed of the car 35·5ft. per second, or 24·2 miles per hour, or 39 km. per hour. The torque curves for these motors with different rotor resistances are given in Fig. 34, showing the resistance per phase that has to be put in the rotor circuit to obtain any required speed. The action of the four motors is regulated by either of the two controllers, that in the forward vestibule being the one generally used. The four stators are connected in parallel, while the four rotors are each connected to four rheostats placed under the body of the car, and electrically independent of one another. The rheostats are worked simultaneously by rods and mitre gear from the controllers, as shown in Figs. 13, 14, 15. The first motion of the controller connects the stators to the line and puts the full resistance in the motor circuits. The subsequent motions gradually take out the resistances, leaving the rotors short circuited. The whole of the electrical equipment of this line was designed, constructed, and erected by Messrs. Brown, Boveri and Co., of Baden, Switzerland.

Automatic Speed Record.—The speed curve of the 3·41 train from Burgdorf to Konolfingen is shown in Fig. 19, which was taken with one of the tachygraphs with which the motorcars are fitted. Vertical distances represent speeds in kilometres an hour; the distance between the horizontal lines is not intended to be equal. The points above and below the record give the time in minutes. On leaving Burgdorf a sharp curve and rise of 1 in 100 reduces the acceleration, which would otherwise be uniform up to full speed, as explained above. Maximum speed is 39 km. or 24·2 miles an hour, and is kept practically constant, the slight variations being caused by irregularities in the track

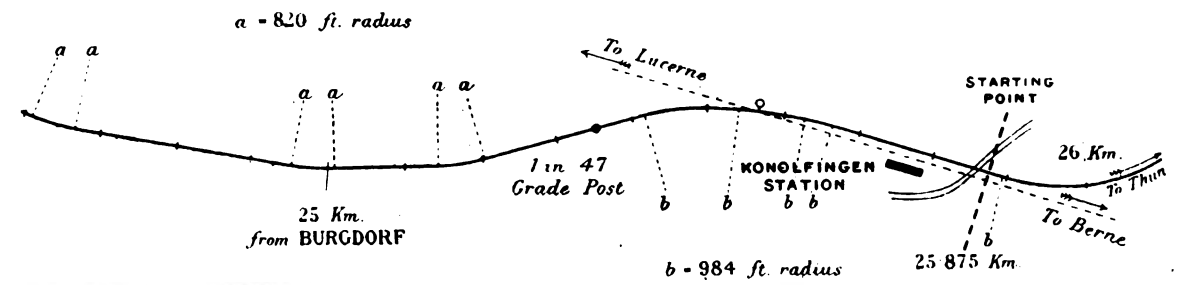

Fig. 5. *Time Schedule.*

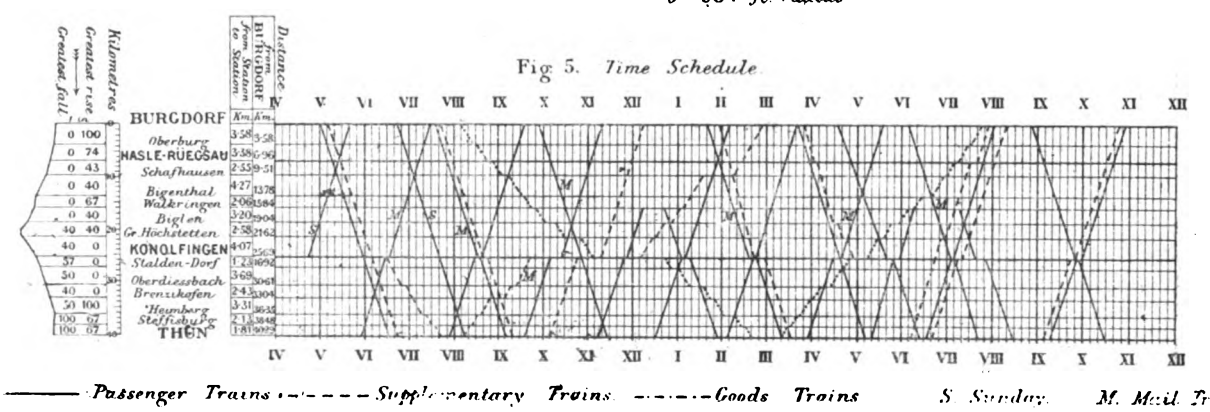

FIGS. 4 AND 5.

Digitized by Google

and varying curves and grades. On leaving Oberberg the record shows where the train left the level and passed on to the grade of 1 in 143, thus making the acceleration curve slightly bend over; the same thing is shown in other places. This record is particularly interesting as showing the actual variations in speed when going up and down the steepest grade on the line. The first part of the distance from Biglen to Gross-Höchstetten is an up grade of 1 in 40; this is followed by a short level stretch and then by a down grade of 1 in 40. The record clearly shows the slight reduction in speed, 2 per cent., on climbing the up grade, then the return to 39 km. an hour on the level, and the slight increase of speed, 2 per cent., on descending the grade of 1 in 40. On leaving Gross-Höchstetten the acceleration curve is markedly increased when the train gets on to the grade of 1 in 40.

The Grades.—These are excessive, and have an important influence on the working of the line. The 32-ton motorcars are each equipped, as explained above, with four 64-h.p. motors. These are able, when acting together, to drive the motorcar itself and one 12-ton trailer up the maximum grade of 1 in 40. If the maximum grade on the line had not exceeded 1 per cent., four more 12-ton trailers, making five in all, might have been added when occasion required. Thus, in attempting to reduce the expense of construction by admitting steep grades, the usefulness of the electrical equipment has been seriously affected. The general impression that it makes no difference how steep the grades are on an electrically-driven line has in this case led to the adoption of such grades as largely to nullify the valuable property of polyphase motors referred to. The practical effect of the grades on the working of the line is that when the capacity of the train has to be increased beyond that afforded by one motorcar and one trailer, in order to deal with a temporary increase in the traffic, a second motorcar and trailer have to be added. (The makers of the electrical equipment are not responsible for this course.)

(To be continued.)

REPORT ON SYSTEMS OF SO-CALLED FREE WIRING.

The following is a supplement to the ordinary monthly report presented by Mr. Hamilton Kilgour, borough electrical engineer, to the Cheltenham Town Council:

It is well known that in most towns the chief obstacle to the general use of the electric light is not the price charged for electric energy, but the preliminary capital outlay in wiring and fittings.

In a town having municipal electric works this condition of affairs is doubly undesirable: firstly, because numbers of ratepayers are unwillingly debarred from fully participating in the benefits of an undertaking expressly intended for the advantage of the town generally, and in which they are practically shareholders; and secondly, because the growth of the undertaking is hindered, with the result that the cost of production and the sale price of electric energy cannot be reduced as much as would be possible if the undertaking had the larger *clientèle* legitimately to be hoped for.

The foregoing considerations have led several municipalities owning electric works to make efforts to assist persons desirous of having electric lighting to acquire installations without having to immediately pay for them in full, and, so far as I have been able to ascertain, with excellent results. Among these municipal authorities are the Hanley, West Ham, Worcester, and, I believe, the Bootle Town Councils, all of whom have been granted sanctions of the Local Government Board to borrow moneys for carrying out their schemes; and the following have also adopted, or are about to adopt, schemes for the same purpose—viz., Barrow, Bolton, Croydon, Dudley, Gloucester, Hoylake, Ilford, Northampton, Shildon, Willesden, and West Bromwich.

There are four different methods possible by which a municipal authority may assist a person to acquire an installation without his having to immediately pay for it—viz.:

The municipal authority may provide, either itself or through a wiring contractor, the installation, and may

(1) Charge, as declared annual rental of the installation, the customer a fixed percentage on the capital outlay;

(2) Charge—and thereby virtually obtain an annual rental for the installation—the customer a slightly increased price per unit for electric energy;

(3) Recover the capital cost, together with the cost of the time accommodation, from the customer by payments at fixed intervals spread over a term of years; or,

(4) The municipal authority may contract with the National Free Wiring Company to act as its collector of a virtual annual rental: the company to provide the installation at its own cost and risk, and the municipal authority to charge the customer a slightly increased price per unit, and to hand over the proceeds of this increment to the price to the company quarterly.

Scheme No. 4 has several rather obvious disadvantages: it introduces, under the most favourable conditions and with authority, a competitor to local wiring contractors; it is apt to lead to excessive competition, and, as a necessary consequence, to bad work; it involves the complication, and the inspection by the company's agent, of the accounts of the electric undertaking; the interests of the company, in respect to the provision of light at a customer's, are not identical, but rather clash, with those of the customer and with those of the municipal authority; the virtual annual rentals obtained from installations which have involved precisely equal capital costs are not necessarily equal, and are often enormously different, since these rentals depend on the candle-powers of the lamps used and on the average numbers of hours the lamps are used per annum.

Schemes Nos. 1 and 2 are open to the objection that the municipal authority has a continuous interest in (to some extent) perishable goods placed on not everlasting premises belonging to others. In both cases difficulties due to faults (from whatever cause), to breakages, and to differences as to what constitutes fair wear and tear, are certain to arise. Of the two, No. 1 is unquestionably the better, since No. 2 has superadded all the disadvantages of No. 4, except those due to the introduction of a formidable competitor to local wiring contractors. Notwithstanding its many disadvantages, Scheme No. 2 has been adopted by more than one municipal authority, and has secured a number of clients.

Scheme No. 3 has the advantage of leaving the customer absolutely free to select his own contractor, and to provide exactly what he desires in the way of an installation: further, the municipal authority is relieved of all responsibility in respect to the contractor's work, and undertakes no risk of loss of capital. The municipal authority under this scheme simply advances, upon approved security and under certain approved conditions, moneys to pay for the installations of intending customers; the scale of payments will provide for the cost of raising the necessary moneys, whether by loan with the sanction of the Local Government Board in the ordinary way or by arrangement with a bank: it is nearly immaterial whether the matter is treated as belonging to capital or revenue account.

After very careful consideration I am strongly of opinion that the committee will do well to adopt Scheme 3, and to take the necessary steps to bring it into useful operation. I am convinced that a scheme of this sort will add many desirable customers to our books, and will result in great benefit both to those whom it is intended to reach and to the electric undertaking.

The details of the scheme I suggest for your consideration are as follows:

1. The minimum value of an installation to be dealt with under this scheme to be £7.
2. The rate of interest charged on outstanding balances, due from the customer to the Corporation, to be about 5 per cent. per annum.
3. The customer to be given, in general, the option of one, two, or three years as the term of repayments, and in special cases—*e.g.*, of very large contracts and of charitable and similar institutions—of one, two, three, four, or five years as the term of repayments.
4. All the payments of each separate customer to be of

Digitized by Google

equal amount; the first to be made immediately after a satisfactory test has been taken and before electric supply is given, and following payments to be made on the next and following quarter-days.

5. The landlord, when possible, to be joined with the customer (if a tenant) in the contract, and in default of this the customer to find security (if required) to the satisfaction of the town clerk.
6. A short descriptive pamphlet and special application form to be issued in connection with this scheme, the former to be generally circulated and the latter to be given to contractors or to intending customers in the manner adopted with the present application form.

The following table gives the amounts of the initial and quarterly payments, and the aggregates of them for the case of an installation costing £100, the payments being spread over one, two, three, four, and five years respectively:

Number of years in term.	Value of each payment. £ s. d.	Aggregate value of payments. £ s. d.
1	20 10 0	102 10 0
2	11 13 5	105 0 10
3	8 5 7	107 12 5
4	6 9 8	110 4 11
5	5 7 6	112 18 2

It will be observed that the total amounts paid in the five cases are almost exactly governed by the following simple rule: for a contract value of £100 add as many fortieths as there are years in the term of repayments, or, in other words, add 2½ per cent. to the cost of the installation for each year in the term of repayments.

Exact compliance with the foregoing rule results in your getting precisely 5 per cent. in the case of a one-year loan, and 4·921 and 4·847 per cent. in the cases of loans of three and five years respectively—the minimum interest you get is nearly 4⅞ per cent. and the average about 4$\frac{15}{16}$ per cent.

I therefore recommend your adoption of the rule of adding 2½ per cent. for each year of the term of repayments.

If you choose to give the customer the option of quarterly, half-yearly, or yearly payments, the only result will be that you will get a slightly higher rate of interest if he pays half-yearly than if quarterly, and again a slightly higher rate if he pays yearly; this is a consequence of his first payment being smallest when the number of payments to be made is largest.

In conclusion, I may draw your attention to two instances in which a scheme of this kind has proved immediately beneficial—viz, Hanley Corporation and the Kensington and Brompton Electric Light Company. In the case of the former, the number of lamps added in the years before and after adoption of the scheme were 5,390 and 7,066 respectively, and the increases in the numbers of units sold per annum 104,000 and 122,000 respectively. In the case of the latter, the lamp increases were 11,100, 13,900, and 15,000 in three following years, and the sold energy increases 168,000, 141,000, and 290,000 respectively.

HAMILTON KILGOUR.

Vienna.—Effective means of preventing future accidents through the breaking of overhead wires in Vienna have been decided upon. All telephone and telegraph wires which cross the trolley wires of the local tramways are to be placed underground, in the form of cables at the point where the crossings occur, as soon as possible. But as it may be some time before the desired change can be effected, temporary protection in the shape of guard wires is to be provided. Moreover, policemen and firemen are to carry pliers with insulated handles, whereby a broken wire may be at once severed. Also all section switches in connection with the trolley lines are to be within arm's reach from the road-level. The measures here enumerated are akin to shutting the stable after the horse has fled. It is a pity that it has required a few fatalities to suggest these elementary precautions, but we are afraid Vienna is by no means the only sinner in respect to this lack of foresight, parallels to which are to be found much nearer home if looked for.

FORTHCOMING EVENTS.

FRIDAY, DEC. 7.

Institution of Electrical Engineers.—At 4 p.m., students' visit to the Electrical Standards Laboratory of the Board of Trade, 8, Richmond-terrace, Whitehall.

Faradian Club.—At 8 p.m., at 8, Charing Cross-road. Lecture on the "Modern Steam Engine," by Mr. J. S. Raworth.

Institution of Civil Engineers.—At 8 p.m., students' meeting. Paper on "Dock Gates," by Mr. F. K. Peach.

SATURDAY, DEC. 8.

Institution of Electrical Engineers.—Students' visit to the Manchester-square Station of the Metropolitan Electric Supply Company.

Institution of Junior Engineers.—Visit, at 3 p.m., to the electric generating station of the London Electric Tramway Company, 88, High-road, Chiswick.

MONDAY, DEC. 10.

Society of Arts.—At 8 p.m., Cantor lecture on "Electric Oscillations and Electric Waves" (lecture III.), by Prof. J. A. Fleming, F.R.S.

Society of Engineers.—At 7.30 p.m., annual general meeting, at the Royal United Service Institution, Whitehall.

TUESDAY, DEC. 11.

Institution of Electrical Engineers (Manchester Section).—At 7.30 p.m., meeting at Owens College. "The Proposed Manchester and Liverpool Express Railway," by Mr. F. B. Behr, with lantern-slide illustrations.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. The following papers will be read and discussed: "The Signalling on the Waterloo and City Railway" and "Note on the Signalling of Outlying Siding Connections," by Mr. Alfred Weeks Szlumper, M.I.C.E.; and "Signalling on the Liverpool Overhead Railway," by Mr. Stephen Butler Cottrell, M.I.C.E.

WEDNESDAY, DEC. 12.

Institution of Electrical Engineers (Glasgow Section).—At 8 p.m., ordinary general meeting. Discussion on the paper on "The Supersession of the Steam by the Electric Locomotive," by Mr. W. E. Langdon.

Society of Arts.—At 8 p.m., fourth ordinary meeting, under the presidency of Mr. R. Brudenell Carter, F.R.C.S. Prof. Frank Clowes, D.Sc., on "The Treatment of London Sewage."

Electro-Harmonic Society.—Smoking concert at St. James's Hall.

Institution of Civil Engineers.—At 2.30 p.m., students' visit to the engine works of Messrs. James, Simpson, and Co., Grosvenor-road, S.W.

Society of Engineers.—Annual dinner.

THURSDAY, DEC. 13.

South-East Coast Institution.—Annual dinner at the Assembly Rooms, Westgate-road, Newcastle-upon-Tyne.

Institution of Electrical Engineers.—Ordinary meeting at the Institution of Civil Engineers. Paper on "The Rapid Variations in the Current through the Direct-Current Arc," illustrated by experiments.

FRIDAY, DEC. 14.

Institution of Mechanical Engineers.—At 8 p.m., ordinary general meeting, Sir Wm. H. White, F.R.S., in the chair. Discussion on Mr. Herbert A. Humphrey's paper on "Power-Gas and Large Gas-Engines for Central Stations."

Institution of Engineers and Shipbuilders.—General meeting in Newcastle-upon-Tyne.

Institution of Junior Engineers.—At 8 p.m., meeting, at Westminster Palace Hotel. Paper, "The Metallurgy of Tin," by Mr. J. H. Davy James.

Physical Society of London.—At 5 p.m., meeting, in Royal College of Science (by invitation of Prof. Rücker). The papers to be read are: "Electric Inertia" and "The Effect of Inertia on Electric Currents in a Rotating Sphere," by Prof. A. Schuster, F.R.S.; "Exhibition and Description of a Quartz-Thread Gravity Balance," by Prof. R. Threlfall, F.R.S.; "On the Theory of Magnetic Disturbances by Earth Currents," by Prof. A. W. Rücker, F.R.S.; "Notes on the Practical Application of the Theory of Magnetic Disturbances by Earth Currents," by Dr. R. T. Glazebrook, F.R.S.; "The New Physical Laboratories of the Royal College of Science," by Prof. A. W. Rücker, F.R.S.; and "Exhibition of a Set of Half-Seconds Pendulums," by Mr. W. Watson. Council meeting at 4 p.m.

Faradian Club.—At 8 p.m., club dinner, at Hotel Florence.

SATURDAY, DEC. 15.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., ordinary meeting. Paper on "Technical Colleges in Germany," by Prof. A. MacLay, B.Sc.

North-East Coast Institution.—At 8 p.m., ordinary meeting at Newcastle-upon-Tyne.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

ELECTRIC RAILWAYS.

The paper read before the Institution of Electrical Engineers last week on the "Supersession of the Steam by the Electric Locomotive," has opened up a discussion on a most important subject. The paper itself shows every evidence of careful preparation, but the fact remains that it is Mr. Langdon's opinion, which should be supported by actual facts. These are available to a large extent from the experiments which have been made in France, and from the actual working over a number of years of short lengths of heavy railways in the States and of longer lines in Switzerland. In England the figures obtained on the Liverpool Overhead Railway and on the deep-level lines in London could be used to support Mr. Langdon's conclusions. All these undertakings, however, have not to do with such heavy and varied traffic as exists on the section of the Midland Railway Company's system between St. Pancras and Bedford. The figures given by Mr. Langdon for the traffic on this section, and of the present cost of working it by steam locomotives, are most useful. Up to the present, also, we have no statements by a supporter of the present steam locomotives that Mr. Langdon's figures are unduly favourable to electric driving. In brief, the conclusions of the paper are that it will take ten thousand pounds per mile to equip main lines for electric power. In this figure the electric locomotives are not included, it being presumed by the author that they will be ordered from year to year instead of steam locomotives, which have each year to be supplemented. From the expenditure of ten thousand pounds per mile, or half a million for the section from St. Pancras to Bedford, Mr. Langdon shows an annual saving of roughly a quarter of a million. This saving is after adding to the expense 3½ per cent. on the additional outlay. About half of this saving is in cost of coal, while the water, oil, and stores required for the locomotives and the repair items are responsible for the rest. From this it will be seen that if Mr. Langdon's figures can only be borne home to the directors of our main lines, there should be no financial difficulty in connection with the conversion of such lines for electrical working. Our object at the present time is not to examine the items of saving in detail, but rather to allude to the important point which is not emphasised by the author. All his calculations are based on the assumption that the traffic after conversion will be the same as the traffic before. This will certainly not be the case, especially on local lines. While at present on these lines it does not pay to run more than a few trains each way per day, the frequency of service with electrically propelled trains can be increased to three or four times the present service. It must be remembered that with electrical propulsion the efficiency and cost per ton-mile is practically the same for a single carriage equipped with motors, as for a heavy train made up of a large number of carriages behind a locomotive or with motors on a number of the carriages. In consequence of this,

Digitized by Google

a frequent service can be provided as cheaply as the present infrequent one, and passenger and goods traffic on these local lines will be largely augmented. It will also react on the main-line trains, so that a considerable increased traffic return will result. We need hardly add that this increased return will be earned with a comparatively insignificant increase in the present large capital of the railway company. As a result, the public will get an improved service and the shareholders of the railways companies a larger dividend.

WIRELESS TELEGRAPHY.

In his second Cantor lecture at the Society of Arts, Prof. Fleming indicated that great improvements had been introduced by Mr. Marconi in his system of wireless telegraphy. It is to be hoped that Mr. Marconi will soon feel able to enlighten the world as to what is being done and what has been achieved. Quite early after the introduction of wireless telegraphy it was pointed out that, while of great value under particular conditions, as a general commercial system it was inapplicable, because each receiver within range of any one transmitter would be affected; hence no message sent could be looked upon as secret. Mr. Marconi has gone a long step beyond this, and we are told that he can now send from one point messages that can only be read by one receiver. We may, without being far wrong, say the instruments are tuned to be in unison. The weak point still is that both transmitter and receiver can be tuned over a considerable range, and while the transmitter is tuned at A to send a message to B, and under ordinary circumstances to B only, the instruments at C, D, E, F, etc., within range, if in the hands of evil-disposed persons, can be tuned similarly to B and E, and all can thus receive from A. Hence there is no absolute certainty of secrecy. If Mr. Marconi has or can improve the apparatus so as to obtain secrecy, not only when secrecy is unimportant, but also when it may be fatal, then he has done something at which the scientific world will wonder. Let us put the matter in another way, if possible, to make it clearer. Assume the analogy to sound to be perfect, and then within certain limits the instrument A can be tuned to produce a required note. B is also so tuned to be in synchronism, and so A and B correspond, while C, not tuned to A's note, does not receive the message. But A can be tuned to C's note, and C to B's, so that interchangeability of receiving and sending is perfectly feasible. The solution required is one which makes it impossible for any person to so adjust C as to enable it to take B's message.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

FATAL ELECTRIC SHOCKS.

SIR,—With reference to the several recent casualties in central stations from accidental contact with exposed parts of switchboards or other high-tension apparatus, I beg to say that by lapping such parts with a special cured rubber strip or splice, such as I am now supplying, they would be rendered quite harmless. I may say, further, that when such material is properly applied, and by slightly warming after each lap or layer, an actual rubber tube results, giving an insulation resistance well up to that of the usual classes of covered conductors in the market. For 'bus bars, etc., where such lapping cannot be applied without dismantling the switchboard, my armalac varnish or paint will also serve well. The makers claim that it gives a resistance equal to the puncture strain of 1,500 volts for each $\frac{1}{1000}$in. in the thickness of the films in which it is applied, hence its great success amongst machine builders here and elsewhere. Whilst, however, calling attention to these most successful materials, I quite agree with the correspondent who wrote about these accidents and suggested that, when possible, gear more modern and carefully designed should be brought into use as the most certain preventive. Still, where such drastic alterations cannot be carried out, the before-mentioned means of insulation may appeal to the engineers of such stations as the next best method of guarding their staff from similar mishaps.—Yours, etc., JNO. J. DOWN.

Harpenden, Herts.

[Mr. Down has shown us the preventives referred to above, and as such they are to be recommended. The faulty design, which is the cause of many fatal accidents, can only be partially rectified in this way. A more drastic course should be adopted to prevent the recurrence of such accidents, and any verdicts reporting that culpable negligence had been displayed would do good.—ED. *E. E.*]

NALDER BROS. AND CO.

SIR,—Notice has recently been published of a report of the liquidator of Nalder Bros. and Co., Limited, who are winding up voluntarily. As some misapprehension may possibly arise owing to the somewhat similar name, we wish to point out that this in no way affects our business, which was purchased some four years ago from Nalder Bros. and Co.; Nalder Bros. and Co., Limited, being of later formation. We shall be greatly obliged if you will kindly publish this.—Yours, etc,

NALDER BROS AND THOMPSON, LIMITED.

London E.C., Dec. 5, 1900

THE INSTITUTION DINNER.

The annual dinner of the Institution of Electrical Engineers was held on Monday last at the Hotel Cecil. The chair was occupied by Prof. John Perry, the president. For the first time in the history of these dinners the company was honoured by the presence of a lady—Mrs. Hertha Ayrton. As Mrs. Ayrton is a full member of the Institution, she was, of course, entitled to an invitation, and her name was duly mentioned in the opening remarks of every speaker. The company numbered about 350, and amongst those present were: Lord Morris, Lord Kelvin, Lord Alverstone, Sir W. MacCormac, Sir A. A. Weldon, Mr. C. E. Spagnoletti, Prof. W. G. Adams, Sir William Corry, Sir E. Carbutt, General Sir R. Harrison, Lieutenant-Colonel R. E. Crompton, Major-General Sir John Donnelly, Sir Courtenay Boyle, Sir J. Kitson, M.P., Sir F. Mowatt, Mr. A. Siemens, Mr. J. Denison Pender, Mr. A. G. Sandeman, Sir A. Geikie, Sir Philip Magnus, Sir Henry Roscoe, Sir W. de W. Abney, Prof. W. E. Ayrton, Sir J. Wolfe-Barry, Sir Andrew Noble, Sir George Kekewich, Sir J. N. Lockyer, Mr. James Swinburne, Sir W. Roberts-Austen, the Hon. Sir D. Tennant, Sir J. Crichton-Browne, Sir H. Trueman Wood, Admiral S. Holland, Mr. S. Z. de Ferranti, Major-General W. Salmond, Sir H. Mance, Mr. R. Kaye Gray, Major-General Festing, Commander G. C Robinson, Mr. S. W. Higginbottom, M.P., Dr. T. E. Thorpe, Mr. J. W. Swan, Dr. Ludwig Mond, Prof. J. M. Thomson, Councillor J. T. Skinner, Bailie A. D. Mackenzie, Mr. A. B. Kempe, Prof. A. W. Rücker, Mr. C. Hawksley, the Rev. C. Stower, and Mr. McMillan. After the dinner and the usual loyal toasts,

Digitized by Google

Mr. S. Z. DE FERRANTI proposed the "Army, Navy, and Auxiliary Forces, including the Corps of Electrical Engineers (Royal Engineers) Volunteers." There were four names on the list to respond to this toast, but the first-named (Admiral Sir W. J. L. Wharton) was not present.

General Sir RICHARD HARRISON, in reply, referred to the fact that two years ago he was present at the dinner when the Electrical Engineering Corps was just inaugurated, and when they were given a *résumé* of the duties of the corps by their commanding officer, Lieut.-Colonel Crompton. Electricity was used in the army for two general purposes at present, the first being the carrying of messages and the second that of giving light. He considered that the military telegraph and telephone system was in a fairly-well organised state, but they had much yet to learn as to the use of electric light in the field. The corps of the Electrical Volunteer Engineers had done good work in this last department, and he considered that their South African detachment had distinguished itself as much as any other force at the front. The good work being done by the corps at home, however, must not be forgotten. He had recently had to inspect a number of coast defences, and was struck by the aid which the corps was giving towards rendering the defence of the British Islands against invasion more certain.

Lieut.-Colonel CROMPTON, replying for the Electrical Engineers (Royal Engineers) Volunteers, said he was proud to be the responsible head of such a corps. The men in Africa had worked well, and Lord Roberts had expressed to him his appreciation of the services rendered. When the corps was formed it was deemed somewhat an experiment to get highly trained and educated men to act in the ranks as soldiers, but the experience in Africa had assured him that the experiment was a most successful one. Not only had they done extensive work as individuals in the telegraph and telephone system connected with the army, but collectively they had done good work with electric light as a means of defence. The engineering education of the men had been very largely used in other departments, and a number of mechanical engineering repairs had been made by them. In fact, there were now eight or ten men still to be kept in South Africa because their services could not be spared. He was pleased to say that the detachment had a larger percentage of men coming home safely than any other contingent. Only four out of a total of eight officers and 58 men had lost their lives. It was not to be inferred from this that they had not held dangerous positions, as the work connected with the military telegraph was almost the most dangerous in the present war.

Lord ALVERSTONE proposed the next toast, which was "Science and Engineering," and referred to the marvellous discoveries in science and improvements in engineering which had been made in the nineteenth century. While these exceeded by a vast amount the inventions and progress of any other century in the past, he would be a bold man who would say that the progress of the twentieth century would not surpass them.

Lord KELVIN responded to the first half of the toast, and in the course of his remarks pointed to the exceedingly rapid growth of our knowledge of electrical subjects. Quoting from Dr. Perry's presidential address, he agreed that there was no record in historic times of any use made of electricity before the present century.

Sir JOHN WOLFE BARRY also replied. Engineers, he said, had been classed by a previous speaker as artists. Unfortunately there was not much artistic merit in certain of our large bridges, and he thought that the chimneys erected in connection with electric lighting stations also lacked, too frequently, any artistic merit. The engineer, however, must remember that there was no need to make his work ugly in order to make it successful. After referring to the interconnection between science and engineering, Sir John Wolfe Barry expressed his belief that the future of civil engineering would be most closely connected with electrical engineering.

Sir JAMES KITSON, in proposing "The Institution of Electrical Engineers," referred to the efforts Parliament had made in the last session to remove legislative obstruction to electrical progress. He hoped that through the expansion of electrical power distribution, engines as small as 10 h.p. and 15 h.p. would soon be things of the past.

Sir COURTENAY BOYLE also joined in proposing the toast, and referred to the great possibilities of electric traction.

The PRESIDENT, in reply, sketched the history, as far as the age was concerned, of telegraphs and telephones, electric lighting, and wireless telegraphy. The lives of these departments of electrical engineering were about 50 years, 25 years, 10 years, and one year respectively—in fact, the electrical profession was still a baby, though a giant baby. They were its nurses, and they were just as ignorant of what their baby was going to be as nurses usually were. They only knew that what they did now would very greatly affect all the future life of the giant. The work of the Institution was growing in quantity and in quality, and the number of their members and the quality of their members were also growing.

The last toast of the evening was "Our Guests," proposed by Mr. JAMES SWINBURNE, and replied to by Lord MORRIS, Prof. RUCKER, and Mr. Bailie MACKENZIE. Lord Morris, in the course of his remarks, called the attention of the engineers present to the large water power which was available in his native country (Ireland), and which he hoped would do much to remake the prosperity of that country, which suffered from the want of coalfields.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following were the candidates balloted for at the ordinary general meeting on Nov. 29:

Members.—Herbert Broadbent, Perth, Western Australia; John Somerville Highfield, Wrindle House, St. Helens, N.B.

Associate Members.—James Anderson, 7, The Parade, Walton-on-Naze, Essex; Arthur Woodroffe Manton, Tudor Lodge, Sylvan-road, Wanstead, Essex; Marcus Nash, Borough Electricity Works, Tunbridge Wells.

Foreign Member.—Otto Peder Kragh, Frederiksberggade, 28, Copenhagen, Denmark.

Associates.—Harry Watkins Kimber, Llanwarne, Kingston-crescent, Portsmouth; Thomas Mills, 43, Claverton-street, Pimlico, S.W.; Arthur Henry Pook, Avondale, Simla, Punjab, India; David Shanks, Newton-chambers, Cannon-street, Birmingham.

Students.—William Beale Cole, Womersley House, Dickinson-road, Crouch hill, N.; John Marshall, 20, Manor-gardens, Holloway, N.; Ernest Ferdinand Motta, Crystal Palace Engineering School, Sydenham, S.W.

THE TRANS-PACIFIC CABLE.

The Colonial Office announces this week that the Pacific Cable Committee have accepted the tender of the Telegraph Construction and Maintenance Company for the manufacture and laying of the much-discussed Pacific cable. The order is given to this company in the names of her Majesty's Government and the Governments of Canada, New South Wales, Victoria, Queensland, and New Zealand. The amount of the tender sent in by the successful company is £1,795,000, and the company has undertaken to have the work completed by the end of 1902. In view of the great length to be laid, this is a reasonable time, but we should not be surprised to hear that the cable will actually be ready for use considerably before it is due. The route taken by this new all-British cable from Canada to Queensland and New Zealand will be *vid* Fanning Island, Fiji, and Norfolk Island. The length from Vancouver to Fanning Island is approximately 3,500 miles, and this section when laid will thus be the longest in the world. The first section to be laid will be that from the Fiji Islands to Australia. The section from Fanning Island to Norfolk Island will be about 1,700 miles, from Norfolk Island to Brisbane 800 miles, and from Norfolk Island to the coast of New Zealand 500 miles. The total length of the cable is to be over 7,000 miles. The value of an all-British connection between Australasian Colonies through Canada to Great Britain

Digitized by Google

cannot be over-estimated in times of peace, and should we unfortunately be engaged in war with any of the Continental powers, the cable may be considered as an absolute necessity. It will be remembered that the present route by which cable messages have to be dispatched involves the calling at a number of ports which are not on English territory. Another important consideration is that the cable will be laid in exceedingly deep water, and hence it will be more secure from interruption. It is to be expected that the exact route will be known only to the Pacific Cable Committee, which, again, will seriously increase the labour of the would-be cable-cutter in time of war.

GLASGOW INTERNATIONAL EXHIBITION, 1901.

As the main buildings of next year's international exhibition are almost complete, the members of the Machinery and Electric Lighting Committee are finding plenty of work to do, and a glance at their share in the organisation of Glasgow s second great show may interest professional readers. The contracts for the fitting up of the wiring and fittings in connection with the electric lighting of the three principal sections have been placed, the successful bidders being Claud Hamilton, Limited, £694. 9s. 6d., for the Industrial Section; and Messrs. Loudon Bros, £327. 11s., for the Machinery Hall, and £214. 17s. for the Grand Avenue. A tender by Messrs. Stewart and Menzies for the supply of steel steam-pipes for £530 has also been accepted. The engineer (Mr. Thomas Young) is now engaged with the scheduling of fittings, etc., required for the lighting of the refreshment rooms, and he has submitted the following additional list of firms who are willing to supply machinery, appliances, etc., on loan: Messrs. Bothman Patent Filtering Syndicate, filters; Messrs. G. MacLellan and Co., high-pressure packing and steam-pipe joints; Messrs. Railton and Campbell, feed-water filter and ash hoist; and British Schückert Company, Limited, 470-h.p. electric pump electric motors, and a searchlight. Mr. Young has been authorised to accept such of the above as he can use.

MANCHESTER.

Under the circumstances now ruling at Manchester in regard to electrical matters, we think the following report of part of the proceedings at the last meeting of the Town Council is interesting.—ED. *E. E.*

Dr. Bishop proposed the adoption of the proceedings of the Electricity Committee, and also that the joint sub-committee, consisting of representatives of the Electricity Committee and the Tramways Committee, be authorised to make final arrangements under the corporate seal with the engineer who may be selected by them to advise the Electricity Committee and the Tramways Committee as to the supply of electrical energy, and to carry out existing contracts and works in progress and in contemplation. He said, with regard to the position of the electricity works, it was not very likely those works would be carried on without interruption during the coming winter, and the Bloom street works would not be in a position to supply current for the tramways till next autumn. A special sub committee of the Electricity Committee had been appointed to confer with a special sub-committee of the Tramways Committee, and they were empowered to take certain steps if necessary. The two sub-committees met, and resolved that the best way of meeting the situation was to call in the aid of an expert who would have the confidence of both committee, and who would undertake the completion of the generating works at the earliest possible moment. That position was practically forced upon them, because the committee had received several resignations during the past few weeks of officials. First, there was the resignation of Mr. Wordingham himself, the chief of the department. Perhaps it would not be absolutely correct to use the word resignation, but Mr. Wordingham had sent a letter to the committee stating that he did not desire his agreement with the Corporation to be renewed, which was practically the same thing. That letter was accepted by the committee. Then a short time ago they received the resignation of the second engineer, who had been appointed as chief engineer at Bolton. Since then the resignation had been received of the superintendent of street mains, which would take effect on Dec. 31. Altogether the circumstances were so peculiar and so urgent that the special sub-committee felt that the only proper way out of the difficulty was to appoint an expert. The special sub committee had interviewed a number of gentlemen whose names were placed before them, but he was sorry to say he was not in a position that day to say that one had been appointed or asked to take up the duties. They thought, however, they would be able to make a selection in a week or two, or earlier if possible. If such a resolution as that he had proposed were not passed, the committee would be thrown a month behind.

Mr. Bowes asked when the recommendation contained in the resolution was made by the sub-committee?

Dr. Bishop said he had only seen it himself a short time ago, when it was placed in his hands. It was a resolution which he thought under the circumstances was justified. He thought it would be a great mistake to postpone the decision for another month.

Mr. Phythian seconded the resolution.

Mr. Alderman Richards said this resolution should have emanated from the committee. It would have been very easy for Dr. Bishop to have called the committee together to sanction it, but not a single member of the committee knew anything about it. A resolution should not be forced upon the Council in this way.

Dr. Bishop pointed out that at the meeting of the committee on Nov. 14 it was resolved that a special sub-committee be appointed to consider the desirableness of calling in an expert to advise the Electricity and Tramways Committees upon the present schemes for the supply of electrical energy, and that they be empowered to act.

Mr. Alderman Richards said the joint conference of the two committees was one thing, and he had no objection to that, but he had an objection to a motion being thrust upon them which had not been passed by the committee. He did not wish the Council to take a leap in the dark.

Mr Alderman Gibson said he did not quite understand why there should be so much hurry. There seemed to be some feeling that they were on the brink of an abyss. Where was Mr. Wordingham? He was not going till March. Had something happened to prevent Mr. Wordingham carrying out the work as he had carried it out before? Could anyone say a word derogatory to Mr. Wordingham's honesty, uprightness, or fitness?

Mr. Lambert said he should like the letter written by Mr. Wordingham to be read, because he wanted to base some remarks upon it.

Dr. Dreyfus thought there was no necessity to read the letter.

The **Town Clerk** read the letter, which was as follows: "As you are doubtless aware, in March, 1897, I entered into an agreement with the Corporation to remain as their electrical adviser for a minimum period of four years from that time. This period expires on March 31 next, and if I desire my engagement to then cease, I have, under my agreement, to give you notice to this effect on Dec. 31, 1900. I am not disposed to continue in the service of the Corporation, and I advise you of this now instead of waiting till December, in order to give you more time in which to make your arrangements. I have managed your undertaking for a period of seven years, and it is only necessary to refer to the published accounts of the department to see that the commercial results have been conspicuously successful, while the undertaking has attained such magnitude as to eclipse that of all others in the country. There are, however, at the present time a number of insinuations being made both in the public Press and elsewhere to the effect that there is something faulty in the management of the department, but whether these allegations are against me personally or against the committee itself I am unable to ascertain. Having in view the services that I have rendered to the Corporation, I think I have a right, especially having regard to the fact that I do not intend to continue my engagement with them, to ask that if the committee have any allegations of any kind to make against me they should definitely state what those allegations are, and give me an opportunity of replying to them. I am not conscious of anything whatever amiss, and if anything definitely is alleged I am confident that I can disprove it, but a vague insinuation no one can meet."

Mr. Lambert said he thought many members of the Council would be indebted to him for asking that the letter should be read, because it put on record very plainly the reason for it. Mr. Wordingham had served the city faithfully for seven years, and he now declined to remain in the service of the Corporation after March 31 while certain insinuations were hanging over his head which had not been brought to any direct charge which he could answer or remove. No one having any regard for his position and reputation could remain in the service of the Corporation without its being stated clearly that there was no reflection upon him and no insinuations made which were not withdrawn. He understood Mr. Wordingham had had no reply to his letter except a formal acknowledgment of it, and no statement had been made to him as to whether these insinuations were persevered in or withdrawn, and no letter had been written to say whether any personal charge was intended to be made against him reflecting upon his capacity, his ability, his integrity, or his honour. That being so, it surely could not be a matter of surprise that Mr. Wordingham should say he did not intend to continue in the service of the Corporation unless these insinuations and charges were withdrawn. (A voice: He did not say so.) The letter spoke for itself. Proceeding, Mr. Lambert expressed surprise that two reports prepared by Mr. Wordingham had not been communicated to the members of the Council, although their substance had appeared in the Press.

Dr. Bishop said the reports in question had not yet been considered by the General Committee because there had been no meeting since they were presented.

Mr. Lambert said the information contained in those reports should be in the possession of every member of the Council before they voted upon the proceedings of the committee. Those reports would convince every member of the Council that Mr. Wordingham, who had designed the scheme and carried it out for seven years, was quite as capable of carrying it out to its conclusion as any expert from either Glasgow or America or anywhere else. He believed Mr. Wordingham would be perfectly willing, and would, indeed, be anxious, for the sake of his own reputation, to carry out and complete the work so long as he was treated in a

Digitized by Google

proper manner and no insinuations made against him of improper conduct. He moved as an amendment that the resolution appointing the sub-committee be altered, and that instead of the words "that they be empowered to act" the words "and to report thereon" be substituted.

Mr. Alderman Richards seconded the amendment.

Mr. Wilson said with regard to Mr. Lambert's statement that Mr. Wordingham would be willing to continue his services if he were approached in a proper manner, no suggestion of that kind had been made either in the Tramways or the Electricity Committee. He thought matters had gone a little too far for that. He urged that any further delay would be a matter of considerable expense to the ratepayers in view of the arrangements made with the Tramways Committee.

Mr. Boyle said the insinuations referred to in the letter existed, he believed, only in Mr. Wordingham's own imagination. No one, so far as he knew, either in the Electricity or the Tramways Committee, had ever framed any charge. The only charge was in so far as the report of the special committee that had been appointed by the Electricity Committee to enquire into the administration of the department reflected upon him. There was in that report no insinuations, but plainly and tersely stated facts. They were not aware that Mr. Wordingham was willing to stay with them, and they were obliged to see to the appointment of the best expert advice obtainable as early as possible. So much depended upon the question under discussion that he thought the committee were entitled to the confidence of the Council in dealing with the matter at once.

Mr. Alderman Hopkinson asked the Council not to create a precedent by giving to a committee, much less a sub-committee, authority to appoint an important officer of the Corporation.

Mr. Plummer suggested that the consideration of the matter should be adjourned for a fortnight.

After some further discussion it was resolved that the consideration of the question be deferred for a fortnight, that the information asked for by Mr. Lambert be furnished to members of the Council in the meantime, and that the Electricity Committee then bring forward a recommendation as to appointing an expert.—*Manchester Guardian.*

LIGHT RAILWAYS.

Notices of intended application under the Light Railways Acts, 1896, have appeared in the *London Gazette* as follows: West Cumberland light railway (syndicate), Hayling Island light railway (syndicate), Bolton, Turton, and Darwen light railway (Lancashire Light Railway Company), Canterbury, Whitstable, and Herne Bay (O. W. Bowen), Crewe light railway (Corporation), Essington and Ashmore light railway amendment and extension (company).

At the last meeting of the Birkenhead Town Council a letter was read from the promoters of a light railway scheme by which it is intended to unite the borough of Birkenhead with the districts of Upton, Greasby, Frankby, Caldy, West Kirby, Hoylake, Meols, Leasowe, and Wallasey, and to run a service of electric cars. The communication was referred to the Tramways Committee.

At the Battle Annual Fat-Stock Show at Hastings it was stated that a light railway from Robertsbridge to Pevensey would soon start.

The Llanfyllin Town Council have appointed a committee to consider whether the Council should offer any opposition to the Tanat Valley Light Railway.

The joint order of the Middlesex Council and the North Metropolitan Company is being drawn up by the Light Railway Commissioners. This is the first order of the kind.

NEW COMMITTEES.

The following additional committees have been appointed:

BOURNEMOUTH.—*Lighting*: Councillor Gunning, chairman. *Tramways and Parliamentary*: Councillor Lawson, chairman.

CROYDON.—*Tramways*: Alderman Sir F. T. Edridge, chairman; Alderman Allen, vice chairman.

EAST GRINSTEAD.—*Special Electric Light*: Mr. Milburn, chairman.

ECCLES—*Public Lighting and Electrical Supply*: Alderman Kendall, chairman; Councillor Oldfield, vice chairman.

HAMPSTEAD.—*Electric Lighting*: Messrs. C. F. Pritchard (chairman), T. G. Randall, G. Buckle, C. W. Cunningham, J. Thwaites, S. Jones, J. E. Bousfield, J. D. Cleaver, W. R. Rea, C. H. Gadsby, and J. Aitchison.

LUTON.—*Electric Light and Power*: Councillor Wilkinson, chairman.

NEWCASTLE—*Lighting*: Alderman Barker Ellis, chairman; Mr. Fred Elliott, vice chairman.

WOOLWICH—*Electricity Supply*: The Mayor (*ex-officio*); Aldermen G. Kelham and J. Harper; Councillors J. J. Clark (chairman), H. S. Syer (vice-chairman), H. J. Butter, J. Illidge, W. Kemp, J. Lawson, P. Pringle, J. A. Turnbull, W. Turner, and J. O. Widger.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

331. Give method employed in calculating resistances for motor starters, so as to get a certain number of amperes per contact. In liquid starters what is the usual current allowed per square inch of surface of iron plate electrode? Also give way of calculating resistance of liquid, say 5 per cent. soda solution.—A. R.

332. In transmitting power to a distance, how does the load factor of the supply influence the commercial result?—P. T.

ANSWERS.

Question No. 325.—While in charge of the controlling board in a high-tension alternating-current station, the shift engineer switched in a machine without synchronising it with another machine on the 'bus bars. The former machine was high-speed—150 amperes at 2,000 volts; the latter being a low-speed—50 amperes at 2,000 volts. After the two machines were connected there was a drop of five volts on the low-tension voltmeter, and although I took all the resistance out of the shunts the voltage slowly dropped, until the light entirely faded out. Then the fuses of the low-speed machine became white hot and blew. Kindly explain the reason for the above.

Best Answer to No. 325 (*awarded* 10*s.*).—It sometimes happens that in occurrences similar to the one in question, some simple neglect on the part of one of the subordinates, which does not at the time come under the notice of the engineer, is responsible for producing an effect which might otherwise be difficult to explain. When synchronising in a lighting station, the machine is generally brought to the proper speed by means either of an arrangement for altering the tension on the governor springs (as in the Willans engine), or else by the use of a by-pass on the steam-pipe. Either arrangement permits the engine to take just sufficient steam for running light with a no-load field on, and if the machine is properly switched in, it will pick up absolutely no load until more steam is given to the engine—we will assume that some such arrangement exists in the plant under question.

Now, we are told that the 150-kw. machine was paralleled, without synchronising, with a machine one-third of its size, and that the low-tension voltage drop was only five at the commencement; so that one cannot help thinking that the shift engineer made a remarkably good chance shot, and that the machine must have been running at very nearly synchronous speed at the time. However, a certain synchronising current flowed which had the effect of dropping the volts, and the switchman increased his exciter voltage in order to bring the 'bus-bar voltage to the normal. The fields of both alternators would in all probability be taken from the same exciter 'bus bars, and consequently both fields would be strengthened. Now, if the engineman, seeing that the big machine had been badly phased, hesitated before giving the engine more steam (and this is not, I think, an unnatural supposition), the effect of the increased field upon the big machine would be to cause it to try to slow up (owing to increased eddy currents), because sufficient steam only was supplied to keep it running at the proper speed with the no-load field. It could not slow up, however, because it was in parallel, and in consequence, as the field was more and more increased, it would make larger and larger demands upon the 50-kw. machine for synchronising current. This would overload the small machine, causing its voltage

Digitized by Google

rapidly to fall, the limiting factor of the amount of current given out being the carrying power of the fuses. When this limit was reached, the fuses blew, as stated in the question. The 50 kw. machine was doing the load by itself before the incident, so that if the 150-kw. machine had been given steam after paralleling it would in all probability have been able to have blown the fuses of the small machine, besides supplying the external load, and that certainly without permitting such a drop in voltage as would cause the lights to die right out.

Of course, the assumptions made may not be correct, but I do not think they are unwarranted, for I personally witnessed a machine which had been rather badly synchronised quickly assume a direct motor current in excess of the full output of the machine, and was at a loss to know the reason for the strange behaviour until it was found that the driver, seeing the machine go in badly, had simply shut the steam off the engine.—W. G. M.

Answer to No. 325 (*awarded* 5s.).—Alternators are said to be synchronised when running at the same frequency and having their E.M.F.'s in the same phase. If the terminals of two such machines be connected by their being switched on to a common 'bus bar or otherwise, any one of three conditions may exist—viz. (*a*) the periodicities may be identical and phase lag 0deg. or less than 90deg.; (*b*) equal periodicities, but phase lag greater than 90deg.; (*c*) the periodicities may be different, and the phase lag have any value from 0deg. to 180deg.

(*a*) In this case, as also in case (*b*), it may at once be noted that since the armatures are running at the due speeds a comparatively small accelerating or retarding force will suffice to alter the phase lag. Let the phase lag

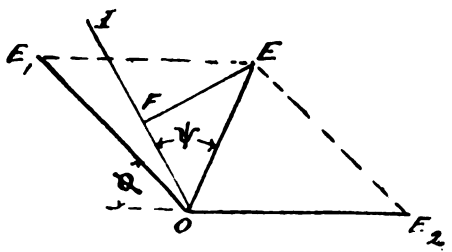

FIG. 1.

be ϕ, the E.M.F. generated in one armature be O E_1, and that at the terminals of the other be O E_2, then the resultant E.M.F. is O E, the diagonal of the parallelogram on O E_1, O E_2. Let the ratio of 2π N L to R in the leading machine = tan ψ, where N = frequency, L = self-inductance, and R = armature resistance. Then O I represents the phase of its current. If E F be drawn at right angles to O I, it is seen that the components of O E are

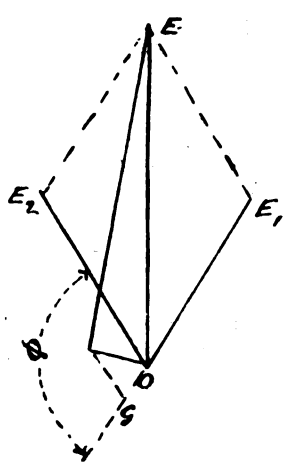

FIG. 2.

E F, the E.M.F. overcoming self-inductance and O F overcoming armature resistance. Now, the power absorbed by the machine from its engine is proportional to the current multiplied by the projection of the armature E.M.F. upon its direction. This obviously increases with the lead, being small when the lead is small, but increasing rapidly with it (see discussion and diagram, Kapp's "Dynamos, Alternators, etc."). Hence, if the engine lags slightly the load is at once reduced and speed maintained. Pushing on is prevented by the augmented load, and altogether the conditions are stable. It is to be noted that in Fig. 1 O E_1 is the E.M.F. of the leading machine, which at a first glance appears to lag owing to the fact that the E.M.F. O E_2 is opposed to its own voltage.

(*b*) In this case the E.M.F.'s at the terminals and in the armatures are, on the whole, in the same direction, and the machines are virtually running in series. The diagram corresponding to these conditions is given in Fig 2. Here the current in machine of E.M.F. O E_1 is in opposition to the induced E.M.F., being proportional to the projection, O G. Hence the watts absorbed are proportional to O E_1 × O G, and the machine runs as a motor. Any increase of lead increases the watts absorbed, lightening the load on the engine. The lead consequently increases to 180deg., the whole current circulates through the two armatures, and the fuses of the smaller machine are blown.

(*c*) In this case the current is driven through the armatures by superimposed E.M.F. waves of unequal frequency. The resultant E.M.F. in machine giving the waves lettered *m* in Fig. 3, is, therefore, the dotted curve

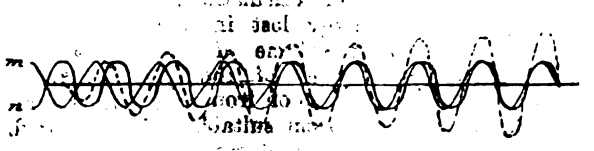

FIG. 3.

whose ordinate at any point is the sum of the ordinates of the induced and terminal E.M.F.'s. The resultant E.M.F. thus varies in magnitude between zero and the sum of the two E.M.F.'s, with a frequency equal to the difference of their frequencies, displaying the phenomenon of "beats." In practice, of course, the fuses of the smaller machine go at or before the first maximum is reached. In the case alluded to in the question it would appear that both machines were about in the same phase when connected, and that the voltage of the less machine was under the terminal voltage; the latter at once falls to about the mean of the machine voltages, so causing the secondary volts to fall. As the phase difference increases, owing to the frequency difference, the state of things explained in case (*b*) is reached. The small machine diverts more and more current from the external circuit until finally its fuses go.—ZERO.

Answer to No. 325 (*awarded* 5s.).—The two alternators were switched in badly out of phase. Their maximum E.M.F.'s would occur at different periods of the cycle. Assuming that they had both correct excitation and speed (the most favourable condition in a case of this kind), the terminal voltage of each machine would be alternately above and below that of the other. The 'bus bars formed a circuit of low resistance between the terminals of the alternators, so that heavy currents would oscillate between the machines, flowing from the machine at higher pressure to that at lower pressure at any instant. Since such large currents were developed in excess of the ordinary output, the machines were not able to meet the demand at full voltage with their proper speed and excitation, this drop in volts being due to (*a*) excessive hysteresis and eddy-current loss; (*b*) an inductive action on the field by the armature coils, choking back the lines of force, both causes being due to the enormous currents flowing.

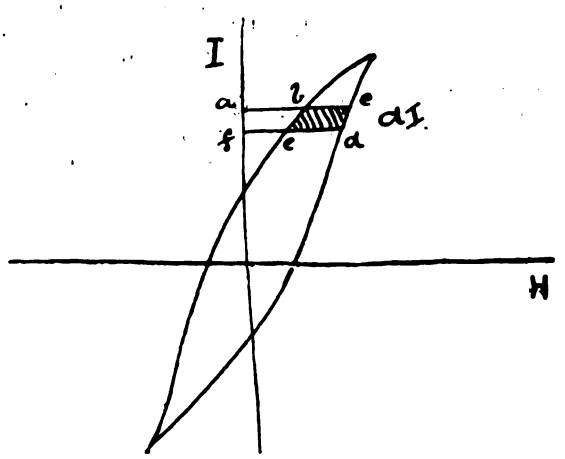
The two machines were alternately motoring each other, for the interaction between the inflowing currents and the field produces a strong forward pull. For this reason the two machines did not shut down even with such heavy currents. The fact that they did not "pull into phase" shows how badly out of phase they were put in. The effect of the motoring current in pulling the rotor of the motored machine forward, combined with that of the generating current of retarding the generator's rotor, has often the effect of pulling these rotors into such a position that the maximum E.M.F.'s of the machines coincide. A heavy rotor is, of course, not so easy to affect in this way. In the given case the machines were so much out of phase that they lost their excitation before they pulled in.

Digitized by Google

It has been mentioned that the large currents produced choke back the field. This, in turn, reduces the terminal voltage. This effect of choking the field will not be seen on the field ammeters, the action being that the field ampere-turns are neutralised by the armature coil ampere-turns. If this action is allowed to go on, the potential on the 'bus bars will, of course, drop, and the lamps, being of high resistance, will go out. The copper 'bus bars, however, are of such low resistance, that large currents at low voltage will flow. In the case cited, a stop was put to the affair by a fuse in the main machine circuit blowing due to these large currents. It speaks well for the construction of the alternators that they stood both the mechanical rocking and the electrical shock and overheating effects so well that the fuse had time to act.—J. A. S.

Question No. 326.—Describe and explain some method of determining the hysteresis loss in the armature of a continuous-current machine.

Best Answer to No. 326 *(awarded* 10*s.).*—The hysteresis loss in the armature of a continuous-current machine may be predetermined by calculation, or it may be found from actual experiment when the machine is run. We will first consider the method of calculation: This consists in summing up the energy lost in a complete cycle of magnetisation for unit volume of iron. This quantity multiplied by the product of the cyclical changes per second and the total volume of iron will give the rate of loss of energy in watts when suitable units are used. If we plot out a cyclical curve of magnetisation giving the relation between I and H, as in figure,



where I = intensity of magnetisation,
H = magnetising force per centimetre of iron.

Then if I and H are in C.G.S. units, the area of the closed figure in square centimetres is equal to the ergs expended in one cycle of magnetism.

Consider an element in figure, d I.

Then work done to magnetise element = H . d I
= area $f d c a$.

Energy given back on demagnetising = area $a b e f$.

$\therefore$ energy absorbed = area $f d c a$ − area $a b e f$.

$\therefore$ total work done = $\int$ H d I.

This expression when integrated between its proper limits gives the area of the closed curve, which is equal to the work done per cycle. If our curve of magnetisation gave relation between β and H, where

β = density of lines per square centimetre; and
H = magnetising force per centimetre of length;
I = intensity of magnetisation, where $I = \frac{\text{magnetic moment}}{\text{volume of iron}}$.

Then, according to Prof. Ewing,

$$\beta = H + 4\pi I,$$

differentiating $d\beta = dH + 4\pi dI$,

multiply by H $H d\beta = H dH + 4\pi H dI$.

Now for a complete cycle $H dH = 0$,

$\therefore H d\beta = 4\pi H dI$;

$\therefore H dI = \frac{H d\beta}{4\pi}$.

$$\int H dI = \frac{1}{4\pi}\int H d\beta.$$

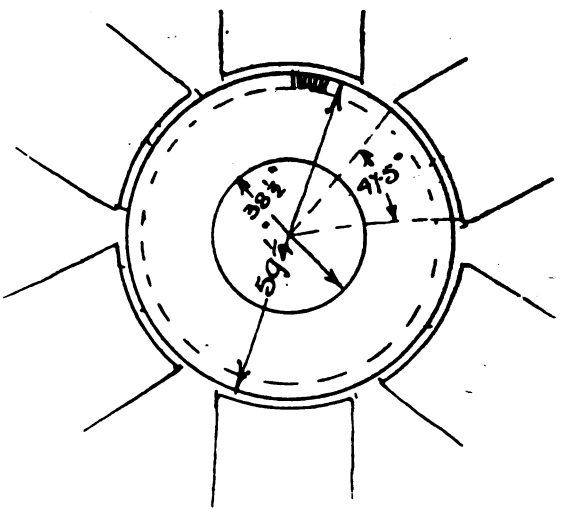
From considerations such as the above empirical formulæ have been deduced, which enable the practical man to determine with comparatively little labour any loss due to hysteresis which he may require to know.

The following formula, based on the experiments and calculations of Prof. Ewing, is found to be sufficiently accurate for calculations connected with soft annealed wrought iron:

$$H = \cdot 003 \times \beta^{1\cdot 6} \times \frown\!\!\smile \times V \times 10^{-7};$$

where H = total watts lost in hysteresis;
β = density of lines per square centimetre;
$\frown\!\!\smile$ = number of complete cycles of magnetisation per second;
V = volume of iron in cubic centimetres.

We will now apply the above formula to a particular case. Consider a six-pole machine with an armature of the following dimensions:



External diameter = 59½in. Internal diameter = 38½in.
Lines per pole = 13·3 × 10⁶.
Effective length of iron between end plates = 9·9in.
Number of lines entering armature from each pole at full load = 13·3 × 10⁶.
Number of teeth of armature under each pole = 29.
Total number of slots in armature = 220.
Size of slots = 1½in. deep × ·416in. wide.

Density of Lines in Teeth—

Area of one tooth at surface = 27·4 sq. cm.
Area of one tooth at the root = 24·6 sq. cm.

Now, as there are 29 teeth under each pole,

Area of surface of teeth under one pole = 795 sq. cm.
Area of root of teeth under one pole = 718 sq. cm.

$\therefore$ Density of lines at surface of teeth

$$= \frac{13\cdot 3 \times 10^6}{795} = 16{,}680 \text{ per sq. cm.}$$

Density at root of teeth $= \frac{13\cdot 3 \times 10^6}{718} = 20{,}000$ per sq. cm.

So that we see that the value of the density in the armature teeth increases as we go from the root of the teeth to the surface; therefore the hysteresis will increase in a similar manner and in proportion to $\beta^{1\cdot 6}$

In our calculations we shall consider the teeth as if they had a uniform density of 20,000 lines per square centimetre. This will give a value for the hysteresis somewhat too high, but it is sufficiently near for practical work.

Density of Lines in the Armature—

Radial section of armature = 565 sq. cm.

$$\therefore \beta_{arm} = \frac{13\cdot 3 \times 10^6}{2 \times 565} = 11{,}800 \text{ per sq. cm.}$$

Volume of Iron in the Teeth—

Volume of one tooth = 109·5 cub. cm.
Volume of 220 teeth = 24,200 cub. cm. (approx.).

Digitized by Google

Volume of Iron in the Armature less that of the teeth = 216,000 cub. cm.

Cycles of Magnetisation—

Revolutions of armature = 135 per minute;

$\therefore \sim$ = revolutions per second × pairs of poles.

$$\sim = \frac{135}{60} \times 3 = 6\cdot75.$$

$\therefore$ hysteresis loss in armature less that of the teeth

$$= \frac{\cdot003 \times 11{,}800^{1\cdot6} \times 6\cdot75 \times 216{,}000}{10^7}$$

$\beta_a{}^{1\cdot6} = 11{,}800^{1\cdot6}$;

$1\cdot6 \log \beta_a = 1\cdot6 \log 11{,}800$;

$= 6\cdot5$;

$\therefore \beta_a{}^{1\cdot6} = 3{,}170{,}000$ approximately.

$H_{arm} = 1{,}390$ watts lost in armature apart from the teeth.

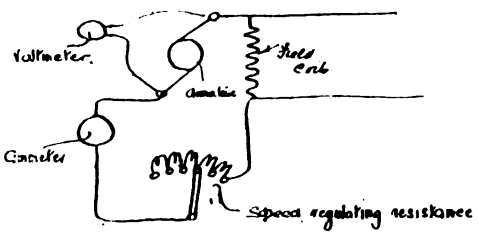
Similarly, hysteresis loss in the teeth

$$= \frac{\cdot003 \times 20{,}000^{1\cdot6} \times 6\cdot75 \times 24{,}200}{10^7}$$

$$H_{teeth} = 444 \text{ watts.}$$

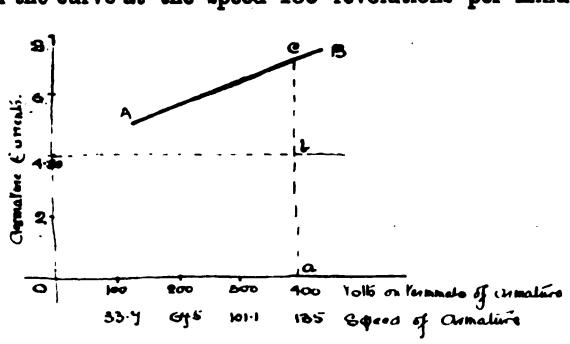
$\therefore$ total loss due to hysteresis in the armature = 1,834 watts.

To obtain the hysteresis loss in the armature of a continuous-current machine by *experiment*. The machine to be tested is connected up to its source of supply, and run as a motor on light load—that is, the motor is doing no external work. The voltage on the field coils of the machine is kept constant, and simultaneous readings of the speed and current in the armature, together with the volts on the armature terminals, are taken for various speeds; the speed is varied by a resistance which is introduced into the armature circuit. The accompanying diagram shows



the connections. The readings taken can now be plotted in the form of a curve, as shown below.

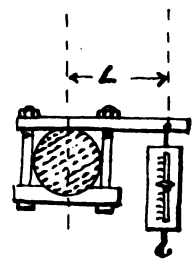
On the ordinates we mark off the armature currents and on the abscissæ the corresponding armature voltages and speeds. Let A B be our resultant curve: produce this so as to cut the ordinate, and at the point of intersection draw a line horizontally. We are now in a position to determine the hysteresis or Foucault current loss in our armature corresponding to any speed and with a fixed normal excitation. For example, find the hysteresis loss in armature from the curve at the speed 135 revolutions per minute.



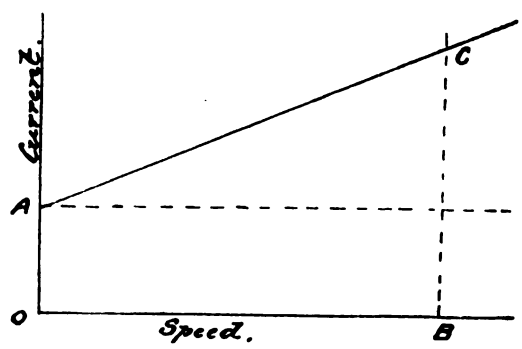
Draw a line vertically from speed of 135 revolutions per minute as in figure; then hysteresis equals $a\,b \times 400$ = 1,834 watts. We may also note that the Foucault current loss is equal to $c\,b \times 400$ = watts. The curve, therefore, enables us to separate the hysteresis from the Foucault current loss. It must be noted that in practice the value we obtain for the hysteresis from a separation curve as just described must of necessity include the energy lost by friction in the bearings, as this quantity, like hysteresis, increases in proportion to the speed.

The importance of this bearing friction may in very small machines be considerable, but with large machines the friction becomes insignificant when compared with the hysteresis loss in the iron core. This bearing friction may be measured independently by driving the machine unexcited and direct coupled to a motor. Then the difference between the power to drive the motor alone and that taken to drive the two machines coupled will give the loss in friction in the driven machine at that particular speed.—H. P.

Answer to No. 326 (awarded 5s.).—The hysteresis loss in a continuous-current armature core increases with the induction. Hence in a series or compound wound machine it increases with the load. To ascertain the energy lost in hysteresis at any particular value of the excitation, a bar may be clamped to the spindle (as shown) and a spring balance attached at some point in its length. The bearings being well lubricated and the magnets unexcited, the armature is slowly rotated by pulling the spring balance round. In this operation care should be taken that the pull on the balance is at right angles to the length of the clamped bar. Let the mean pull indicated on the balance for a complete revolution be P pounds. If the point of attachment of the balance be L inches from the centre of



spindle, the frictional torque is P L inch-pounds. Let, now, the field be switched on and adjusted to the excitation required. The turning is repeated, and some greater mean pull, P′, is indicated. The corresponding torque, P′L, is equal to the combined friction and hysteresis torque. Thus the hysteresis torque alone is (P′ − P) L inch-pounds, and the loss in horse-power is $2\,\pi\,n\,(P' - P)\,L \div (12 \times 33{,}000 = \frac{(P - P)\,L\,n}{63{,}000}$ horse-power $= \frac{(P' - P)\,L\,n}{84\cdot5}$ watts, where n denotes revolutions per minute. The principle of this method is that in carrying the iron of the core through a complete cycle a definite amount of work—viz., the "hysteresis loss" for one cycle—must be done. Now, the work done in a complete revolution by a torque is $2\,\pi$ times that torque. Hence, deducting for friction in the journals, the two expressions are equated, and the loss per revolution is found. This loss per revolution is within practical limits independent of the rapidity of reversal, and consequently the loss in n revolutions is n times that in one. Another method, which the writer judges more satisfactory, is to supply current to its brushes and run the armature light as a motor. The losses are now threefold: (*a*) friction, (*b*) hysteresis, and (*c*) eddy currents, the first two of which are proportional to the speed, and the last to the square of the speed. The magnets are separately excited to



the required extent, and the speed, current, and voltage across the brushes are noted. By varying this voltage, and consequently altering the other quantities, a number of corresponding values of the current and speed are obtained.

Digitized by Google

If these speeds be set out as abscissæ and current as ordinates, a straight-line curve is given; for the currents being small, the voltage applied across the brushes is practically the back E.M.F. of the machine. The curve produced back to cut the axis of current intercepts a length O A, so giving the value of the current that would just overcome frictional and hysteresis resistance to motion, assuming the former to have a constant value at all speeds. The product of this current and the voltage is the watts expended at any speed on friction and hysteresis. If it is desired to separate these losses, the armature may be rotated with unexcited magnets through some form of transmission dynamometer, and the friction loss so determined; or the following method may be adopted: Let the armature be rotated at speed N, and suddenly thrown free so that it rotates by its own inertia, gradually slowing down. If in the first minute after release it makes N' revolutions, as recorded by a speed indicator, its speed at the end of the minute is $N-2(N-N')=2N'-N$. Let these letters refer to the case when the magnets are not excited, and N, N'' denote speeds similarly with the field on. Then, roughly, since work done in equal tim s is proportional to differences in the square of the velocity, we have the relation—

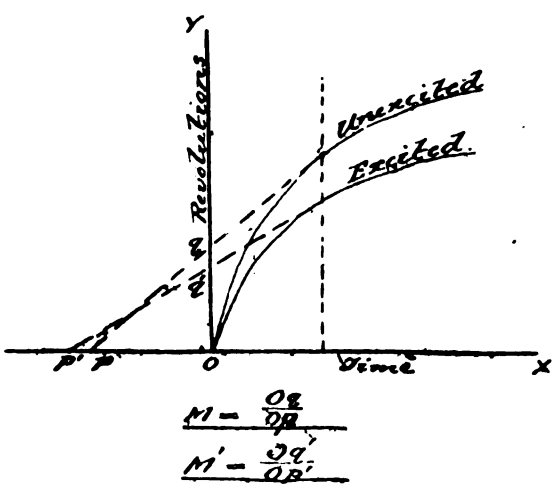
$$\frac{\text{Work lost in friction}}{\text{Work lost in friction, hysteresis, and eddies}} = \frac{N^2-(2N'-N)^2}{N^2-(2N''-N)^2} = \frac{N'(N-N')}{N''(N-N'')} = K$$

Hence, if B C be the current at any speed O B, the total loss, W, = B C × brush volts. The loss in friction and hysteresis = $\frac{O\,A}{B\,C}$ W, and the loss in friction alone = K W, so that

$$\text{Hysteresis loss in watts} = \left(\frac{O\,A}{B\,C} - K\right)W.$$

This method is subject to the error that the eddy-current loss is assumed to be the same per revolution for both N and N'', whereas it actually varies as their squares. If, however, N'' is not greatly different from N, the error is not considerable.

A more accurate form of the above method is to note times and revolutions made, counting each from the instant of throwing off the belt, and doing so both for excited and unexcited magnets. Two curves may then be set out as



shown. Let a straight line parallel to O X be drawn cutting the curves in points such that the value of the time is small, and at each point let a tangent be drawn to the curve. Then the intercepts on O Y, divided by the intercepts on O X, give the velocity in each case after the same number of revolutions have been made. If these be M with unexcited magnets and M' with excitation on, then

$$K = \frac{N^2 - M^2}{N^2 - M'^2},$$

and the further calculation is as given above.

From the form of the question, it is assumed that no sample of the core discs used is available. Were such at hand, the hysteresis loss per cycle per unit volume might be determined by any of the usual methods, and this, multiplied by the volume of iron in the core and by the speed would give the total loss.—ZERO.

Answer to No. 386 (*awarded* 5*s.*).—Leaving out of account all methods depending on measurements made on the armature iron before it is built up into a core as being quite unreliable, the following is probably the simplest and most direct method of measuring not only the hysteresis but also all the other losses occurring in the armature. For this test the machine should be run as a motor, with the field separately excited so that the voltages across armature and across shunt are separately variable. The measurements to be taken consist of readings of armature volts, armature amperes, exciting amperes and speed, with the machine running at three different speeds and with three different exciting currents at each speed, making nine complete sets of readings as a whole. More readings may, of course, be taken, but these nine are usually quite sufficient to draw all the necessary curves accurately. The speeds and excitations should be selected as far apart as possible, so as to cover the whole range of speed and excitation respectively. The current required in the armature will generally be so small that the loss in the copper (C^2R) in the armature will be negligible compared with the total input watts, so that the readings may be taken to equal the losses in bearings, brushes, windage, hysteresis, and eddy currents only. In order to separate these various losses, the nine readings should be plotted as shown in Fig. 1, using exciting amperes as the abscissæ and input watts (or total losses) as the ordinates. In this way three curves, one for each speed, will be obtained, shaped approximately as in Fig. 1.

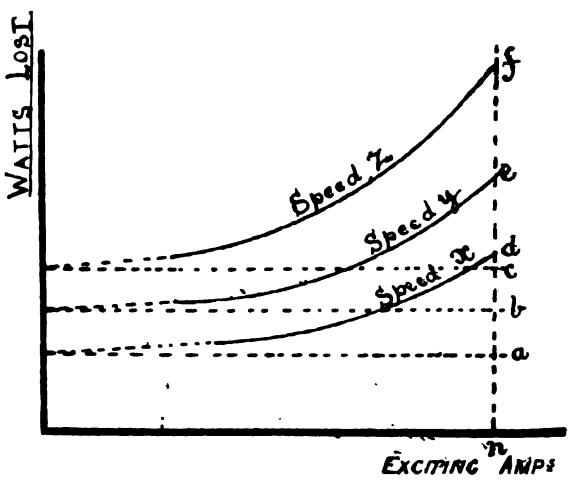


FIG. 1.

These three curves must then be produced backwards till they meet the vertical axis, as shown by the dotted portions in Fig. 1, and from the three intersections so obtained the horizontal lines, *a*, *b*, and *c*, should be drawn. The watts represented by the heights of these lines above the horizontal are the bearing friction, brush friction, and windage losses at the three speeds, since they represent that portion of the loss which is unaffected by the excitation. The remaining watts, lying between the horizontal lines, *a*, *b*, *c*, and the total loss curves, *d*, *e*, and *f*, respectively, are the hysteresis and the eddy-current losses at the different speeds.

These last two losses can further be separated from one another by drawing the curve shown in Fig. 2. This separation depends on the fact that whilst the hysteresis watts are proportional to the speed of the machine, the eddy-current losses are proportional to its square. Further, since hysteresis is proportional to the 1·5th or 1·6th power of the induction density in the iron, whilst eddy-current losses are proportional to its square, it is evident that the relative proportions of hysteresis and eddy-current loss depends on the excitation, and therefore a separate curve, similar to Fig. 2, must be drawn for each excitation for which the separation is required. Fig. 2 has the speed of the machine for the abscissæ and "core loss per revolution" for the ordinates. This "core loss per

Digitized by Google

revolution" is simply that portion of the total loss which lies above the horizontal line in Fig. 1, divided by the corresponding speed in revolutions per minute. Thus, if Fig. 2 is drawn for the exciting current marked n in Fig. 1, the values of "core loss per revolution" for the points marked P, Q, and R in Fig. 2 will be $\frac{a\,d}{x}$, $\frac{e\,b}{y}$, and $\frac{f\,c}{z}$ respectively. Having got the points, P, Q, and R, which will usually lie on a sloping straight line, produce the line backwards to cut the vertical axis, and from this point of intersection, r, draw the horizontal line $r\,t$ (Fig. 2). Then the height, $o\,r$, of the horizontal line represents the hysteresis loss [and $o\,r \times$ (speed in revolutions per minute) is the hysteresis loss at that speed] and heights above the horizontal, such as t R, represent eddy-current losses [and t R × (speed z in revolutions per minute) = eddy-current watts at speed z].

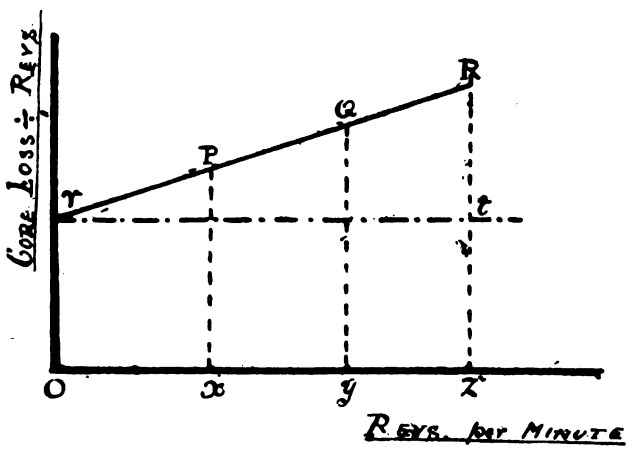

Fig. 2.

The above test is a fairly simple and reliable one, and the only valid objection to it is the fact that the core losses are only measured at *no load*, or practically no load, and it is an ascertained fact that these losses always increase somewhat with the load on account of armature distortion. There is no way of avoiding this difficulty entirely, though, of course, the actual total losses (not separated) at full load may be obtained by a Hopkinson or other similar efficiency test.—Q.

NEW COMPANIES.

The following new companies have been registered:

Whittaker Bros., Limited.—Capital of £75,000. Object: to adopt an agreement with J. H. Whittaker and B. W. F. Whittaker, and to carry on at Dudley, Kidderminster, and elsewhere the business of an electric light and power company (including telegraphy and telephony) in all its branches.

Electric Lighting Boards (British Manufacturing Company), Limited.—Capital of £75 000 in £1 shares. Object: to adopt and carry into effect an agreement made by this company with the Electric Lighting Boards, Limited, etc.

New Century Arc Light Company, Limited.—Capital of £30,000 in £1 shares. Object: to adopt an agreement with W. G. Davis, and to carry on the business of electricians, etc.

Lyndhurst Electric Lighting and Traction Company, Limited.—Capital of £500 in £1 shares (250 founders'). Object: to construct or acquire, equip and work railways and tramways, to supply electricity, etc.

Improved Nut Works, Limited.—Capital of £10,000 in £1 shares. Object: to carry on the business of bolt and nut manufacturers, mechanical and electrical engineers, etc.

Simms Manufacturing, Company, Limited. — Capital of £25,000 in £1 shares. Object: to adopt agreements (1) with F. R. Simms and (2) with Bryan Donkin and Clinch, Limited, and to carry on the business of motor, motor and other carriage builders, electricians, etc.

Isidor Frankenburg and Co., Limited.—Capital of £25,000 in £10 shares. Object: to acquire the business carried on by S. Frankenburg at the Greengate Rubber Works, Greengate, Salford, Lancashire, and to carry on the business of a manufacturer of and dealer in waterproof, rubber, and leather goods and electric cables.

Holden Motor Patents Syndicate, Limited.—Capital of £10 000 in £1 shares. Object: to carry on the business of vehicle builders, electricians, electrical and general engineers, etc.

Crown Electric Heating Syndicate, Limited.—Capital £5,000. Object: to adopt an agreement with A. R. Leask and H. Stewart, and to carry on the businesses of electricians, electrical and general engineers, suppliers of electricity for light, heat, power, etc.

George Scott and Son (London), Limited.—Capital of £15,000 in £1 shares. Object: to acquire the business carried on at 44, Christian-street, London, and 67, Lord-street, Liverpool, as George Scott and Son, to adopt an agreement with F. W. Scott, and to carry on the business of mechanical, electrical, and general engineers, etc.

Workington Iron Ore Company, Limited.—Capital of £125,000 in £1 shares. Object: to adopt and carry into effect an agreement for the acquisition by purchase or otherwise all or any part of the business and property of the Workington Hematite Iron and Steel Company; to develop the resources of land and other rights in any part of the world; to construct railroads, telegraph systems etc.

LEGAL INTELLIGENCE.

O'REILLY v. DUBLIN UNITED TRAMWAYS COMPANY.

This case was called in the Queen's Bench Division No. 1, before the Lord Chief Baron and Mr. Justice Andrews last week, when **Mr. J. F. Murphy**, on behalf of the defendants, moved to have the action remitted to the Recorder of Dublin. The plaintiff, Anne O'Reilly, a vegetable dealer, sought damages for personal injuries caused by the alleged negligence of the defendant's servants.

Mr. Gordon, manager of the tramway company, stated that on Sept. 1 last the plaintiff, who had a donkey and cart, was selling vegetables at the Botanic-road, Glasnevin. The motorman sounded the gong, and the plaintiff turned the donkey's head towards the footpath, with the result that the back of the cart collided with the tramcar. The motorman said that on the return journey he saw the plaintiff engaged at her work.

The Plaintiff denied that the motorman had sounded the gong. After the occurrence she was conveyed to the Mater Hospital. She had to remain in bed for several weeks. An affidavit from the doctor who had examined her stated she had sustained permanent injury, but counsel considered that affidavit vague, as it did not specify how she had received permanent injury.

The Court refused the motion, with costs.

CLAIM BY ELECTRICAL ENGINEERS.

In the Westminster County Court on Wednesday, before his Honour Judge Lumley Smith, Q.C., and a jury, the case of Cunnington *v.* Frazer was tried. It was an action by the plaintiffs, Messrs. Cunnington, a firm of electrical engineers carrying on business at 98, St. Martin's-lane, W.C., to recover the sum of £14. 12s. 9d., in respect of electrical work done and fittings supplied to the order of the defendant in his capacity of proprietor of the German club in Soho.

Mr. Alfred Raven was called, and said he was in the employ of the plaintiff firm, and took the order for the work in question from the defendant. It was duly carried out, and the charges made were very low. The defendant had been applied to for payment on several occasions, but for some reason or other he had not settled the matter.

Mr. F. W. Cunnington said the charges which the firm had made were very reasonable, and he could not understand why the defendant took exception to them.

The defence was that the work was defective, and that one of the electroliers which the plaintiffs fixed up over the billiard table fell down and injured the cloth, and in respect of this a counter-claim was put in for damages.

Mr. Jas. Grant, an electrical engineer, of 63, Queen Victoria-street, said he had been called in by the defendant to examine the plaintiffs' work. He had gone carefully through the whole of the items, and his estimate worked out at £8, including profit.

After hearing the evidence of other witnesses **his Honour** said he was not satisfied that the work was badly done, nor did he think the charges were too high; therefore judgment would be for the plaintiffs on the claim, and also on the counterclaim, with costs.

MRS. LEITCH v. NATIONAL CONDUIT AND CABLE COMPANY, LIMITED.

There was an action set down for jury trial before Lord Kyllach on Wednesday, in which Ann Hay or Leitch, 152, Watt-street, South Side, Glasgow, sued the National Conduit and Cable Company, Limited, for £500 damages for personal injuries sustained on Oct. 14, 1899, by falling over a heap of granite chips lying in Watt-street, and which had been placed there by the defenders. The case has been settled by the defenders paying the pursuer £150 and expenses.

ROBBERY FROM A TELEPHONE WORKS.

At the Halifax Borough Court, Collingwood Haigh, of Garden-street, who was remanded a week ago on the charge of failing to answer a witness summons, was on Friday charged with being implicated along with a man named Burnham in a robbery from

Digitized by Google

the National Telephone Company's premises in Raglan-street on Sept. 11 last. Burnham had already been committed to the sessions for trial along with two other men named Simpson, who were charged with receiving the stolen property.

Mr. J. E. Farrar appeared for the prosecution, and applied for another remand for a week. He was in communication with the Telephone Company, and the case was not yet completed. The accused left the town after the robbery, and had since been wandering about the country.

The Bench granted a remand, but decided to allow the man out on bail in two sureties of £10 each.

COMPANIES' MEETINGS AND REPORTS.

LANCASTER AND DISTRICT TRAMWAYS.

The annual meeting of the Lancaster and District Tramway Company was held at the Corn Market-street Coffee Tavern, Lancaster, on Saturday.

Mr. A. Bell (chairman), who presided, said he agreed it would be to the advantage of the inhabitants of Lancaster, of the Corporation, and of the shareholders of the Tramway Company if the negotiations for the acquisition of the undertaking by the Corporation in connection with their scheme of electric tramways were reopened. If those negotiations were reopened and conducted on a sensible businesslike basis, he had good hopes that they would result in a settlement. He saw no reason why, when they on the one hand were willing to sell, and sell at a reasonable price, and the Corporation on the other hand were willing to buy, and to buy at a reasonable price, they should not come to a satisfactory settlement. They knew as well as he that no settlement could be arrived at by the directors without a full and thorough consultation with themselves.

The balance-sheet was adopted, and Messrs. John Slinger and R. Nicholson were added to the directorate to assist in any negotiations with the Corporation.

KALGOORLIE ELECTRIC POWER AND LIGHTING.

The report, to be submitted to the meeting on 10th inst., states that the progress of the operations of the Corporation from unforeseen causes has been considerably delayed, partly on account of the difficulty of finding a suitable site for the plant and buildings contemplated. It is now found that instead of £150,000 producing a plant of 4,500 i.h.p., it will cost the Corporation £135,000 to erect a plant capable of producing 2,400 i.h.p. The Corporation's consulting engineers estimate that the net earnings on this plant will be about 16 per cent. on £200,000. The directors recommend the immediate erection of the plant. A supply of water has been cut amounting to 24,000 gallons per 24 hours, which is considered sufficient for the Corporation's needs. In sinking the well a lode formation was intersected which by assay showed gold. Should good lodes be bisected in cutting the reservoirs, it is the intention of the Board to form a separate syndicate, or company, to develop the mining rights.

KEIGHLEY TRAMWAYS.

At the annual meeting last Friday the **Chairman** stated that the negotiations between the Corporation and the directors of the Company had not proceeded beyond the initial stage, and it was not possible to make any statement. Before anything definite was done the sanction of the shareholders would be required, and a special meeting would be called. However, he had no doubt there would be electric cars in Cavendish-street before very long.

Mr. Herbert Haggas and Alderman B. S. Brigg were re-elected directors, and Mr. J. R. Whitley was re-elected auditor.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

Directors: Hon. Henry Marsham (chairman); Major Leonard Darwin; A. Weston Jarvis, Esq.; Matthew Gray, Esq. (managing director); Abraham Scott, Esq.; S. Wm. Silver, Esq.; Robert Kaye Gray, Esq. (engineer-in-chief).

Report of the directors for the year ending Sept. 30, 1900, to be presented at the thirty-seventh ordinary general meeting of the shareholders, to be held at the Cannon street Hotel, on Thursday, Dec. 13, 1900, at 12 noon:

The accounts show, after provision for doubtful debts, a net profit for the past 12 months of £67,238. 18s. Adding £31,511. 8s. 10d. brought forward, and deducting £12,500 interim dividend paid in June, there remains a disposable balance of £86,250. 6s. 10d. The directors recommend the distribution of a dividend of 15s. a share, free of income tax, amounting to £37,500, making, with the interim dividend paid in June, a total payment of 10 per cent. for the year, and leaving £48,750. 6s. 10d. to be carried forward. The general business has been fairly profitable, although the price of raw material continued high. The cable steamer "Buccaneer" has been employed on charter to the Western Telegraph Company, and the ss. "Silvertown" laid a cable between New York and Canso (Nova Scotia) for the Commercial Cable Company. Since the closing of the financial year the manufacture and shipment of another cable for the same company has been completed, and the ss. "Silvertown" is now awaiting orders to proceed with the laying between Waterville (Ireland) and Weston-super-Mare. The works at Silvertown and Persan have been maintained in their usual state of high efficiency. The employment of electricity for the transmission of power in the former is being extended. The Board has sent a representative to South Africa with a view of opening an agency there. Major Leonard Darwin and Mr. Robert Kaye Gray, the retiring directors, offer themselves for re-election.

BALANCE-SHEET.

Dr. Capital and Liabilities.	£	s.	d.
Authorised share capital	812,000	0	0
Share capital—amount paid on issue of 50,000 shares of £10 each	500,000	0	0
Mortgage debentures	300,000	0	0
Reserve fund	450,000	0	0

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Kendal.—The Electric Lighting Committee will shortly advertise for tenders for Contracts Nos. 1 and 2.

Blackpool.—The Corporation invite tenders for the supply of arc lamp carbons and oils for one year. Tenders by Dec. 17. Details in our advertisement columns.

Brighton.—The Council invite tenders for the construction of the permanent way of the tramroads. Tenders by Dec. 18. Details in our advertisement columns.

Aberdeen.—The Electric Lighting Committee invite tenders for the supply and erection of storage batteries. Tenders by Dec. 22. Details in our advertisement columns.

Leigh.—The Electricity and Tramways Committee invite tenders for the supply and erection of electricity mains. Tenders by Dec. 17. Details in our advertisement columns.

Hendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Swindon.—The Corporation invite tenders for three high-speed triple-expansion steam dynamos, one balancer, and one motor-generator. Tenders by Dec. 24. Details in our advertisement columns.

Harrogate.—The Corporation invite tenders for two high-pressure 30ft. by 8ft. 6in. Lancashire boilers, with fittings complete, and economiser. Tenders by Dec. 25. Details in our advertisement columns.

Bristol.—The Electrical Committee invite tenders for induced-draught plant, steam and electric feed and general service pumps,

Digitized by Google

and water-softening plant. Tenders by Dec. 20. Details in our advertisement columns.

Battersea.—The Council invite tenders for the supply of ordinary and prepayment electricity meters, in accordance with specification No. 10. Tenders by Feb. 1, 1901. Details in our advertisement columns.

Swansea.—The Public Library Committee invite tenders for the electric wiring and fitting of public library, schools of science and art, and art gallery. Tenders by Dec. 17. Details in our advertisement columns.

Brighton.—The Council invite tenders for the supply of unarmoured and armoured lead-covered electric cables during the year ended Dec. 31, 1901. Tenders by Dec. 24. Details in our advertisement columns.

Middleton.—The Corporation invite tenders for superheaters economisers, feed pumps and pipes, tanks, steam and exhaust pipes, valves, and accessories. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Leigh.—The Electricity and Tramways Committee invite tenders from manufacturers for the supply of 1,000 220-volt incandescent lamps during a period of 12 months. Tenders by Dec. 17. Details in our advertisement columns.

Ilford.—The School Board invite tenders for wiring and all ordinary fittings for about 200 lamps at 16 c.p., the Higher-Grade School, Melbourne-road, Ilford, Essex. Tenders by Dec. 17. Details in our advertisement columns.

Rathmines.—The Electric Lighting Committee invite tenders for the supply and erection of various plant for the extension of the municipal electricity works. Tenders by Jan. 10, 1901. Details in our advertisement columns.

Glasgow.—The Caledonian Railway Company invite tenders for telegraph and electrical appliances. Specifications, etc., may be obtained from Mr. J. Lorimer, stores superintendent, Charles-street, St. Rollox, Glasgow. Tenders by Dec. 17.

Boxhill.—The Council invite tenders for the supply, delivery, and erection of a water-tube boiler and pipework and one 150-kw. steam dynamo at their electricity supply station. Tenders by Dec. 10. Details in our advertisement columns.

St. Pancras.—The Guardians of the Poor invite tenders for the installation of the Cook's-terrace Infirmary, Pancras-road, N.W., with electric light, according to drawings and specification. Tenders by Dec. 20. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for the whole of the work necessary in erection of buildings for new electric light station, Hylton-road. Particulars, etc., may be obtained at the Borough Electrical and Tramway's Engineer's Office, Dunning-street. Tenders by Dec. 10.

Leigh.—The Electricity and Tramways Committee invite tenders for the supply and delivery of the following motors and starting switches: one 10-h.p. motor, four 3-h.p. motors, three 2-h.p. motors, and three 1-h.p. motors. Tenders by Dec. 17. Details in our advertisement columns.

Tooting.—The Metropolitan Asylums Board invite tenders for the execution of certain wiring and other works in connection with the proposed electric light installation at the asylum now in course of erection at Tooting Bec. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Aberdeen.—Tenders will be invited shortly for the following plant for the Dee village station: Two surface condensers, with air and circulating pumps, £3,297; boilers, with heating surface of 17,112 square feet, £9 760; fuel economiser of 800 pipes, £1,500; storage battery, £5,120—total, £19,677.

Ayr.—The Tramways Committee invite tenders for Section 2, overhead work: Part 1, poles, centre and side brackets, section boxes, etc.; Part 2, complete overhead electrical equipment; Section 3—underground work: supply of feeders, distributors, telephone cables, conduits, trenching, etc. Tenders by Dec. 14. Details in our advertisement columns.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Alteerig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berenteen, British Vice-Consul, Stavanger.

Winwick (near Warrington, Lancs.)—The Committee of Visitors for the County Asylum invite tenders for (Contract No. 3) wiring, etc., including ring main and feeders, sub-main, lamp circuits, switchboards, distribution boards, fittings, etc. The drawings, etc., can be inspected at Winwick Hall, and also at the offices of the architects, Messrs. Crisp and Oatley and W. S. Skinner, Edinburgh-chambers, Baldwin-street, Bristol. Tenders by Dec. 29.

RESULTS OF TENDERS.

Colchester.—Two coolers, etc., have been ordered, at a cost of £386 each, from Messrs. Klein, Limited.

Gillingham.—The Electric Lighting Committee have arranged with the electric lighting company to supply the nine arc lights in the High-street at a cost of £18 each per annum.

Beetle.—The Committee have accepted the tender of the Electric Construction Company, at £2,263, for a Belliss triple-expansion engine and E.C.C. dynamo. Sixty-five tenders were received.

London County Council.—The Council have accepted the tenders of the Dermatine Company, Limited, for the supply of indiarubber goods; and Messrs. Middleton Bros., for oils and lubricants.

Rhyl.—The tender of Messrs. W. Thornton and Sons, 38 Wellington-road, Toxteth Park, Liverpool, has been accepted at £6,225, for the erection of refuse destructor and electric light station buildings, together with a chimney 120ft. high.

Metropolitan and District Railways.—The Directors of the Metropolitan District Railway and the Metropolitan Railway Companies have received numerous tenders for supplying electricity on the portions of the underground railway selected for this purpose. These were opened on Tuesday, but no decision was arrived at.

Keighley.—The following tenders have been accepted; Chamberlain and Hookham, Birmingham, 140 electricity meters, £551; Lancashire and Cheshire Opalite Tile Company, Limited, Manchester, tiling engine-room walls, £390; Gardner, Sons, and Co., Limited, Bristol, wrought-iron window frames, £80. 2s.; Edmondson Bros., Keighley, plasterers' work, etc., £129. 1s. 10d.

Aberdeen.—The Electric Lighting Committee have accepted the following tenders: Mavor and Coulson, Limited, 47, King-street, Mile End, Glasgow, two 200-kw. direct-coupled continuous-current generators and one 120-kw. balancing set; Johnson-Lundell Electric Traction Company, Limited, 16A, Soho-square, London, W., one 420-kw. direct-coupled continuous-current generator.

Pacific Cable. The Pacific Cable Committee have accepted, on behalf of her Majesty's Government and of the Governments of New South Wales, Victoria, Queensland, New Zealand, and Canada, the tender of the Telegraph Construction and Maintenance Company for the manufacture and laying of the projected Pacific cable. The amount of the tender is £1,795,000, and the work is to be completed by the end of 1902.

Mexborough.—The Council have accepted the following tenders: Tinkers, Limited, Hyde, Lancashire boiler, £532; Mavor and Coulson, Limited, Glasgow, steam dynamos, balancer, booster, feed heater, and pump, £1,786. 14s.; B. Thomas, Manchester, switchboard and connections £355, battery connections 3s. 7d. per yard; Aehmore, Benson, Pease, and Co., Stockton, storage battery, £1,050; Callender's Cable Company, Limited, mains, £5,585; Chatteris Engineering Company, Chatteris, five-ton crane, £127. 10s.

Leeds.—The City Council have accepted the following tenders, amounting to a total of £72,943. 13s., for the extension of the electric lighting station on the Britannia Mills site: P. Rhodes, excavator, mason, and bricklayer, £42,977. 17s.; J. Moulson and Son, carpenters and joiners, £4,000; Phœnix Foundry Company, ironfounders, £17,975; J. Atkinson and Son, slaters, £330; G. Thompson, plumber and glazier, £3,359; T. Cordinglay and Sons, plasterers, £527; A. and S. Wheater, concreters, £3,296; J. W. Walton, painter, £478. 16s.

Cardiff.—The Tramways Committee have received the following tenders for cables for tramway purposes: British Insulated Wire Company, £22,166 (accepted); Callender's Cable Company, £23,614; W. T. Glover, £23,468; Henley's Telegraph Company, £23,628; Johnson and Phillips, £24,007; St. Helens Cable Company, £24,065; Siemens, Limited, £22 656; Telegraph Manufacturing Company £23,702; Union Cable Company, £24,762; Western Electric Company, £22,667. For a tramway crane, Joseph Booth, of Leeds, at £865, was accepted. Bruce Peebles and Co.'s tenders of £1 041 for a motor-generator, and £1,260. 10s. for a Tudor storage battery, have been accepted.

BUSINESS NOTES.

TRACTION.

Southend.—The new tramways were started on Monday.

Birkdale.—The introduction of trams into this district is being urged.

Willesden.—A poll will be taken early in January with reference to the tramways scheme.

Kingston.—It has been decided that the poll on the tramways scheme should take place.

Irthlingborough.—Stoney Stanton granite and Mountsorrel paving setts are to be used for the new tramway route.

Worthing.—The Town Council are considering an electric tramways scheme, estimated to cost from £80,000 to £100,000.

Aberdeen.—It has been decided to at once double a number of lines. We understand that an American contract for rails has been accepted.

Birkenhead.—Mr. Arthur R. Fearnley, manager of the Bradford Tramways Company, has been appointed tramway manager at a salary of £300 a year.

Wandsworth.—From the last proceedings of the Council it appears that the London County Council's Tramway Bill will meet with considerable opposition.

West Ham.—The Town Council have now definitely resolved that granite pitching be used on all the lines of tramways, subject to the resolution already passed as to wood paving in front of buildings used for public meetings.

Digitized by Google

West Bromwich.—It is believed that the South Staffordshire Tramway Company are now prepared to negotiate with the Corporation as to the sale of their lines.

Beetle.—Colonel Trotter inspected the Derby-road and Rimrose-road tramway last week and approved same. This route consists of 1½ miles of double track, with span wire.

Gravesend.—The promoters of the local tramways have decided to register a company and to obtain final understanding whether or not the Corporation would furnish the current.

Manchester.—With regard to the change in tramways from horse to electric traction now in progress, we learn that the new permanent way is being laid at the rate of a mile per week.

King's Norton.—A meeting of ratepayers have agreed that consent should be given to promote a Bill enabling the Council to construct tramways within the urban district and any adjoining districts.

Leamington.—It is reported that difficulties have arisen between the Leamington Corporation and the tramway company with regard to the agreement to equip the present tramways on the overhead electric trolley system.

Torquay.—The Electric Lighting Committee have appointed Messrs. Kerswill, Ball, Beavis, Taylor, R. Smerdon, Bowden, and Person to consider the electric tram question. Refuse destructor complaints have been received.

Wortley.—The Tramways Committee of the Leeds Corporation have decided to proceed with the work of laying the lines for electric traction as soon as possible, the new line forming a junction with the existing line at the Crown Inn.

Levenshulme.—The District Council are calling the attention of the Manchester Corporation to the Council's request to be informed of the negotiations which had taken place in regard to the purchase of the tramway lines in the district.

Stoke-on-Trent.—The notice of the Potteries Electric Traction Company of application to the Light Railway Commissioners for an order authorising the construction and working of light railways in the borough has been referred to a committee.

Halifax.—It is proposed to rescind a former decision of the Council to amalgamate the duties of the Electricity and Tramways Committees, and instead thereof to amalgamate the duties of the Electricity and Gasworks Committees as heretofore.

Darwen.—The Town Council have advanced the salary of the electrical engineer by £50 per year, and also granted him an honorarium of £50 for services rendered in connection with the conversion of the tramways from steam to electric traction.

Barrow.—The Board of Trade have sanctioned the use of steam power on the tramways till February only. It is proposed to substitute electric traction, but the terms between the Corporation and the British Electric Traction Company have not yet been agreed upon.

Nottingham.—It is now stated that everything in connection with the new tramways system has been completed except the cars. The bodies of the cars are in the shed, but the equipment is not complete. As soon as the cars have been completed they will be set running.

Dover.—The petition by drivers and conductors for increases of pay, reduced hours, annual holiday, superannuation fund, and other matters has been settled by the acceptance of a report by the general manager recommending that there be no addition to present cost of staff.

Cumberland.—We notice that an extensive scheme of electric tramway and tramroad on the west coast of Cumberland, extending over 30 miles, has been deposited in Parliament. Messrs. Bennett and Ward Thomas, of Manchester, and Mr. A. M. Fowler, M.I.C.E., of Westminster, are the engineers.

Bristol.—The extension of the electrical system of the Bristol Tramways Company is now practically completed. No date has yet been fixed for the inspection of the permanent way by the Board of Trade official but the inspection of the power station and the various electrical appliances has been made.

Cycle and Motorcar Exhibition.—In consequence of the great success of the National Cycle and Motorcar Exhibition at the Crystal Palace, recently completed, we understand that the directors of the show have already arranged with the directors of the Palace to hold their tenth annual exhibition in November, 1901.

Dundee.—The provisional order for tramway extension and street improvements, application for which is about to be made by the Town Council to the Secretary for Scotland, is noteworthy, inasmuch as it is, if not the first, one of the first of such applications that have been made in terms of the Private Legislation Procedure (Scotland) Act, 1899.

Walker.—The District Council will not discuss the question of the proposed new electric tram service until next month, as they are at present negotiating with the Newcastle Corporation upon a similar subject. The promoters of the scheme propose to institute two quick services of electric trams, one running along the high road and the other by the riverside to Shields.

Blackburn.—The new electric cars purchased by the Corporation continue to arrive at the depôt in Simmons-street During the week several of the new cars have been on the Darwen and Blackburn tram routes, and the journeys have been successful. Ere long the Blackburn public will have the whole of the cars at their service, and a thorough system will be in operation.

North Wirral.—One outcome of the complaints made by the Hoylake and West Kirby District Council recently about the railway service to and from Liverpool, and the assertions of several councillors that any opposition would receive large support, has been the projection of a scheme for connecting the Deeside district with Seacombe and Birkenhead by a system of electric tramways.

Water Power at Snowdon.—A scheme has been deposited in Parliament for utilising the water power near the foot of Snowdon to work an electric light railway to Port Madoc to open out the mineral district, and also to facilitate the excursionists and pleasure seekers in the season. Messrs. Bennett and Ward Thomas, of Manchester, and Mr. A. M. Fowler, M.I.C.E., of Westminster, are responsible for the work.

Darlington.—With regard to the Town Council's wish to purchase the present tramways in certain contingencies, and lay down an electric system, the General Purposes Committee now recommend that professional advice be called in to ascertain the approximate value of the present tramways, which are owned by the Imperial Tramways Company, and also to report on the cost of constructing electric tramways and the probable receipts from the same.

Hampstead, Euston, and Charing Cross Railway.—The proposed extension of this electric railway to Hendon and Finchley by tunnelling under a portion of Hampstead Heath is likely to meet with great opposition at Hampstead. The railway is not objected to *per se* but the threatened interference with Hampstead Heath is, especially as there seems to be no reason why the line should not go under the public roadways instead of under the Heath.

Burnley.—Representatives of the Padiham Urban District Council are about to confer with the Corporation Tramways Committee respecting the reconstruction of the tramway in the Padiham district. The Standing Sub-Committee were authorised to meet the Padiham representatives. The borough surveyor is about to advertise for tenders for electric cars, and the Electricity Committee will now take steps to enable them to supply electrical energy for the tramways.

Wigan.—A conference will be held to-day between representatives of the Ince and Hindley Urban District Councils and the Corporation to discuss the question of the purchase by them from the Corporation of so much of the tramways as are situate in their respective districts. The following have been appointed as engineers-in-charge on the terms of a recent advertisement: Messrs. S. Lees, Bradford; W. Abraham, London; H. Lamb, Preston; and A. Granger, Morecambe.

Chester-le-Street.—The Highway Committee of the District Council have recommended that consent be given to an application by the United Kingdom Tramway and Light Railway Electrical Syndicate, Limited, for the consent and support of the committee for the promotion of a provisional order under the Tramways Act, 1870, for the construction of tramways on the overhead electric trolley system from Penshaw Bridge through Washington and New Washington, along the Washington New-road, being a continuation of the Easington, Houghton, and Sunderland scheme.

Chester.—The Town Council have passed the requisite statutory resolution as to tramways as follows: "That application be made to Parliament in the ensuing session for a Bill to confer powers on the Corporation of Chester to reconstruct the existing tramways in the city of Chester, to construct additional tramways in and adjacent to the city, to work tramways, and for other purposes, and that the costs and expenses attending the promotion of such Bill be charged on the borough fund." A meeting of ratepayers on the 4th inst. approved of the promotion of the proposed Bill.

Liverpool.—The new regulations of the Liverpool Tramways Committee with respect to penny stages came into operation on Saturday, and, generally speaking, afforded considerable satisfaction to the travelling public, although in several districts grumbling is yet heard as to the inequality of the intermediate stages. It is expected that on Sunday next the extension to Seaforth will be available for traffic, and by another week Mr. Bellamy, the manager, hopes to have the belt line encircling the whole city open for the car service, so that then the entire system will be practically completed.

Lowestoft.—The Corporation have passed a resolution to promote their Tramways Bill, which includes the confirmation of any agreement made with the National Electric Traction Company, Limited, with reference to the leasing of the proposed tramways, also power to make further provision in regard to the tramway undertaking, and to enact provisions incidental to the funds; and further provision in regard to the electric lighting undertaking of the Corporation, and, amongst other things, to empower them to supply electricity in bulk beyond the borough, and to supply electrical fittings.

Warrington.—The British Electric Traction Company, Limited, have submitted to the Tramways Committee proposals for leasing the Warrington tramways, the consideration of which has been postponed. A proposal having been made by the promoters of the Warrington and Northwich light railway that the Corporation should join in the application for the order, the Corporation have resolved that it was inadvisable for them to join in the proposed application for the light railway order; and that in order to preserve the entire control of the tramways within the borough, no running powers over them be granted to any company.

Newcastle.—The Tramways Committee have just made an official inspection of the work in progress. The committee determined that the work in the heart of the city should be stopped during the winter months until spring-time, immediately after the junction at the foot of Northumberland-street and in Grainger-street was completed. The contractor, however, was authorised

Digitized by Google

to go on with the work in outlying districts in the meantime. Much satisfaction was expressed at the work done by the contractor as to material and workmanship, and more particularly were the committee pleased with the sections by the Town Moor and around St. George's Church and Osborne-road.

Gosport.—The District Council and the Provincial Tramways Company have come to a sort of deadlock. In accordance with a recent resolution of the District Council, Mr. Palmer, the clerk, attended at the London office of the company, and tendered the notice that the Council meant to take possession of the tramways under the Act of 1870. The secretary, however, declined to accept the notice as valid, upon the ground that the meeting at which the Council's decision was arrived at had not been called in accordance with the terms of the Act. A long and costly litigation is now threatened, and the points in dispute being questions of law, the case may be carried to the Court of Appeal and the House of Lords.

Southport.—Another section in the tramway system of the Corporation has been opened for use, this being the line from the markets to Ash-street, thus completing what is called the inner circle, a distance of nearly three miles, for which the fare is one penny. A 12 minutes' service will be run each way, with supplementary cars to the infirmary and Kew Gardens when that section is completed. Preliminary arrangements are in progress for the construction of an electric line of railway, which is to be laid on a plateau near the edge of the line of sandhills, thus connecting Formby-by-the-Sea with Birkdale and Southport. A new motor engine is being put down at the electricity works at Blowick to complete the three which were originally ordered for motive purposes. It is expected to be ready for working at Christmas.

Bournemouth.—Mr. Peers, in his report on the lighting of the workhouse, pointed out that the supply could be provided by an engine and dynamo of 13 b.h.p. or 14 b.h.p., but the engines and dynamos in his scheme were of 27 b.h.p. One of these engines and dynamos would form a spare set in case of a breakdown. As, however, he understood the Guardians contemplated extending their laundry, he would recommend them to fix a boiler, say 18ft. long by 5ft. 6in. in diameter, instead of the smaller 10ft. boiler in his schemes. Such a boiler would give ample margin for the laundry requirements, and would only add £70 or £80 to his estimate; but if the larger boiler were adopted it would be necessary to rebuild the existing chimney stack, and make it 60ft. or 70ft. high. The report is to be discussed at the next meeting of the Guardians.

Little Lever.—The District Council have approved the minutes of committees stating that a letter had been sent to the Farnworth and Radcliffe Urban District Councils asking whether those authorities would agree to certain terms as to the leasing of the lines and the payments in respect thereto in the event of the Little Lever Council obtaining a provisional order enabling them to construct a line in their own district connecting the systems of the Farnworth and Radcliffe Councils. Deputations from those authorities attended the meeting and made counter proposals, which were left over for consideration by the General Purposes Committee of the Little Lever Council. In answer to an application by the Lancashire Electric Power Company, the committee expressed their willingness to grant an easement at a rental of 5s. per annum, subject to the company bearing the costs of an agreement for protecting the Council's interests for the laying of a water-main along Hall lane and Tong road.

Wimbledon.—At a meeting of the Urban District Council last week the Tramways Committee presented a report dealing with the scheme for the construction of two miles of local tramways, which the Council at their last meeting decided to include in their Improvement Bill. The report referred to the fact that the principle of the scheme had received the sanction of the London County Council, the Croydon Rural District Council, and the Mitcham and Merton local authorities, and a letter was read from Mr. J. Clifton Robinson, managing director of the London United Tramways, Limited, asking to be allowed to compete for the leasing of the lines when powers had been obtained. The sum of £32 000 was given as the estimate for the cost of the lines in the event of their being constructed by the Council and afterwards leased to a company, and £57,000 in the event of the Council deciding to construct and work the lines themselves. Another £20,000 would be required for street widenings. A motion to proceed with the scheme was rejected by one vote.

Walsall.—At the meeting of the Town Council on Monday next the General Purposes Committee will recommend that the common seal of the Council be affixed to the conveyance from the South Staffordshire Tramways Company to the Corporation of the tramways undertaking in the borough, and to an assignment of the Birchills tramways depôt; also to a lease of the tramway lines to the South Staffordshire Tramways (Lessee) Company, Limited, in accordance with the terms of the agreement with the company and the provisions of the Walsall Corporation Act. The same committee will recommend that the duty of repairing and maintaining the tramways be added to the borough surveyor's department, and that the necessary plant and material be purchased, at an estimated cost of £1,000; also that the following tramways be laid down and equipped by the Council: along Lichfield-road to Walsall Wood; in High-street and Stafford-road, Bloxwich, as far as Little Bloxwich-lane; along Bridge-street, Ablewell street, and Birmingham-road for a length of one mile from Lichfield-street; from Park-street along Wolverhampton-street and Wolverhampton-road as far as Willenhall. It is proposed that the borough surveyor and electrical engineer prepare the necessary specifications, estimates of cost, etc.

Middlesbrough.—At a meeting of the Streets Committee of the Corporation on Friday, a report was read from Lieut.-Colonel Von Donop, R.E., who was appointed by the Board of Trade to inspect the uncompleted portions of the tramways. It stated that with regard to the uncompleted Zetland-road section, and the end of the Linthorpe line, he was of opinion that the inconvenience caused the public was not sufficient to justify the Board of Trade in pressing the company to carry them out. With reference to the Zetland-road section however, this decision only applies to the existing state of affairs; if the projected extensions beyond Nos. 5 and 6 tramways are carried out, the question of the completion of the Zetland road section should then be reconsidered. It was stated that Sir Courtenay Boyle had ordered the Tramway Committee to proceed with the line from the ferry to the exchange, and said that if it were not done the consequence would be serious. Sir Courtenay intimated that the company must at once prepare the line from the ferry, and that they would be given another six months to complete it. A long discussion arose, during which it was urged that the Corporation should insist upon the penalty per day for the non-completion of the lines. Ultimately it was left with the committee to draw up a letter to the Board of Trade.

New Issue.—The South Lancashire Electric Traction and Power Company, Limited, which has been formed with a share capital of £850 000, divided into £600,000 in 6 per cent. cumulative preference and £250,000 in ordinary shares of £1 each, together with £750,000 in 4½ per cent. first mortgage debenture stock, are now making an issue of the whole of the debenture stock and £400,000 of the preference shares at par. The company propose to acquire and develop as parts of a single system the concessions and rights obtained by the South Lancashire Tramways Company and the Lancashire Light Railways Company, taking over the whole of the issued shares in both undertakings and thus obtaining exclusive control. Thus a complete system of electric traction in South Lancashire will be rendered possible, with cars running at frequent intervals between Liverpool and Manchester through Prescot, St. Helens, Newton, Earlestown, Leigh, and Eccles, and with branch connections from the main line to Wigan, Bolton, and other important centres. The purchase price has been fixed at £350,000, payable as to £50,000 in cash, £50,000 in preference shares, and the balance in ordinary shares. The South Lancashire Tramways Company was formed by the South Lancashire Tramways Act, 1900, which authorised the construction of electric tramways between St. Helens and the Manchester district by two main trunk lines, one from Haydock, passing through Ashton-in-Makerfield, Abram, Hindley, Westhoughton, Little Hulton, and Walkden, to Swindon, where it meets the tramways leased to the Salford Corporation; and the other from St. Helens, through Earlestown, Newton-in-Makerfield, Lowton, Leigh, Atherton, Tyldesley, Boothstown, and Worsley, to the boundary of the borough of Eccles, where it also meets the tramways leased to the Corporation of Salford; branch lines also connect Lowton with Golborne and Abram, Hindley with Atherton and Tyldesley, Worsley with Swinton, and the borough of Bolton with both Westhoughton and Atherton. Powers will be sought next session for the Liverpool and Prescot light railway extensions. Order was granted in 1898 to the Lancashire Light Railway Company, Limited, the whole of whose shares will be held by this company. The line, nearly 3½ miles in length, will commence at the end of the St. Helens tramway system at Prescot and terminate at the city boundary of Liverpool at Knotty Ash, to which point it is expected that the Liverpool Corporation's electric tramways will shortly be completed. The application had the support of all the local authorities of the districts through which it passes, but its special importance lies in the fact that it must form the connecting link between the two tramway systems of Liverpool and St. Helens, and through the latter with the South Lancashire systems to Manchester and district. Although granted under the Light Railway Act, it is for all practical purposes a tramway, and its construction will be the same as that of the South Lancashire tramways. The St. Helens tramways, which are leased to the New St. Helens and District Tramways Company, Limited, lie between the Liverpool and Prescot light railway and the South Lancashire tramways, and connect the two. A continuous route will thus be available from the tramway system of Liverpool to that of Manchester, and to the whole of the places served by and in connection with the South Lancashire Tramway Company's system. The St. Helens Company has undertaken to grant facilities for an interchange of traffic Every class of goods will be carried on the tramways and light railway. The South Lancashire Tramways Company is empowered by its Act to supply electric energy to local authorities for all purposes, and arrangements will be made accordingly.

LIGHTING AND GENERAL.

Croydon.—Application is to be made for a loan of £5,000 for free wiring.

Newcastle.—The better lighting of Grey-street is being considered by the Town Council.

Hull.—The new street between Monument Bridge and Prospect-street is to be lighted by electricity.

Warrington.—Mr. William H. Grimsdale has been appointed electrical engineer to the Corporation.

Grimsby.—The question of the Corporation taking over the telephone system has been postponed for a time at least.

Aberystwyth.—Mr. Preece is being consulted with reference to the proposed new agreement with the electric lighting company.

Digitized by Google

Criccieth.—The report of the Electric Lighting Committee on electric lighting is being discussed in committee by the Council.

Saltburn.—The electric lighting company have declined the Urban District Council's offer of £8,000 for the purchase of their plant.

Edinburgh.—The advisableness of extending the electric light along Albert-street from Easter road to Leith-walk is being considered.

Commercial Cable Co.—The directors have declared a quarterly dividend of 1¾ per cent. and a bonus of 1 per cent. on the capital stock, payable 2nd prox.

Cardiff.—Owing to the appointment of Mr. Appelbee to Ashton, the Council are reopening the question of combining the lighting and tramway departments.

Hanley.—Sanction has been received for the borrowing of £5,000 for electric lighting purposes and £9,500 for the erection of a refuse destructor at Sandyfield.

Helensburgh.—The proposal to obtain a provisional order for the introduction of electric lighting into the burgh has been abandoned by the Commissioners.

Ilkley.—A deputation of the District Council is to confer with Mr. Gibbings and others who are applying for a provisional order to light the district with electricity.

St. Helens Cable Co.—The Company having declared a dividend of 6 per cent. on their share capital, now notify that the transfer books will be closed until the 10th inst.

Wrexham.—Mr. Sillery, the newly-appointed electrical engineer, will commence duties on Jan. 1. The Town Council have obtained a loan of £5,000 for electric lighting.

Pemberton.—We note that the Urban District Council are inviting offers of a loan of £20,000 on the security of the general district rate and the electric lighting undertaking.

Doncaster.—The Town Council's electricity works are making very satisfactory progress. The committee have applications for 8,300 lamps, and the price is to be only 5d. per unit.

Bournemouth.—The County Borough Council are about to consult an expert with regard to the application of the Bournemouth and Poole Electricity Supply Company, Limited.

East Ham.—Lieut.-Colonel A. C. Smith has held an enquiry into the application of the Urban District Council for sanction to the borrowing of £2,640 for purposes of electric lighting.

Bedford.—The mains for private lighting are to be extended along Goldington-avenue, Kempston-road, Woburn-road, The Avenue, Ampthill-road, and Victoria-road at an estimated cost of £1,150.

Burnley.—The Rural District Council have decided to receive a deputation from the Reedley Hallows Parish Council with regard to obtaining a provisional order to forward electric lighting powers at Reedley, east of the canal.

Derby.—The Electric Lighting Committee have ordered plans and specifications of a new chimney, etc., at the electric light station, to be prepared by Mr. A. Eaton, architect, who was employed as architect for the recent extensions.

Water-Softening Plant.—We note that an order for the "Archbutt-Deeley" water-softening plant has been placed with Messrs Mather and Platt, Limited, by the Electrical Power Distribution Company for their works at Sutton.

Stock Exchange Settlements.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the London United Tramways, Limited, 4 per cent. first mortgage debenture stock.

Worthing.—It appears that over 100 applications were received for the post of resident engineer of the new Worthing Corporation electric lighting works. Mr. G. Porter, of the Westminster Electric Supply Corporation, has been recommended by the Town Council for the appointment.

Fife.—At a recent meeting of the Fife or Turriff Committee applications by the National Telephone Company for permission to erect poles were granted, subject to the provision that the poles could only be erected within the burgh of Turriff with the approval of the Commissioners.

Colchester.—The Town Council have fixed the price of current at 2½d. per unit for motor purposes. A report from Mr. Sillar, the electrical engineer, recommending various alterations of and additions to the plant has been adopted, and application is to be made for a loan of £12,000.

Wombwell.—A letter from the South Yorkshire Electric Lighting Company giving notice of intention to apply for power to erect an electric lighting plant at Wombwell, and to supply the district with electricity, is being considered by the Gas Committee of the Urban District Council.

Keighley.—The Town Council have appointed a deputation to wait upon the management of the National Telephone Company at Bradford for the purpose of urging upon the company the desirability of a modification of the charges in connection with their telephone system in this borough and district.

Sheffield.—It appears that on Friday quite a succession of faults occurred in the cables in the neighbourhood of Broomhill and Glossop road, and customers were for three, four, or five hours plunged in darkness. Gangs of men were out all Saturday night, and again on Sunday, and nearly all the customers were reconnected.

Eastbourne.—The Chamber of Commerce have passed a resolution in favour of the establishment of a municipal telephone exchange for the borough. Plans for the new electric light station have been approved, and the borough engineer has been instructed to prepare the specification and bill of quantities and invite tenders for the same.

St. Pancras.—The Electrical Engineer reported at the meeting last week that by Christmas he anticipated they would have reached the maximum load they could deal with through the existing mains, and he produced a scheme for increasing the capacity of the feeders and extensions at an estimated cost of £29,390. The matter was referred to the Finance Committee.

Inverness.—At a recent meeting of the Town Council, it was agreed to settle the account of Mr. Craven, Edinburgh, the engineer for the abandoned electric lighting scheme, by a payment of 2½ per cent. on £27,000, the estimated cost of the scheme. Letters from two private companies offering to purchase the right of providing electric light for the town were remitted to a special committee.

St. Marylebone.—At a meeting of the Council last night a letter was read from the Metropolitan Electric Supply Company calling the Council's attention to the arrangement made with the Vestry in 1896 for the experimental lighting by electricity of the upper part of Regent-street, and stating that they are prepared to enter into an agreement for an adequate scheme of public lighting in the borough.

York Minster.—The electric light installation for the choir and lady chapel of York Minster has now been completed, and was used for the first time last Sunday. There are 170 lights, extending in rows along the whole length of the choir and lady chapel, and clusters of lamps are suspended from the triforium; the latter are 32 c.p. each. The south choir transept is also lighted by electricity, and the crypt will shortly be wired.

Aberdeen.—On Wednesday Councillor Kemp, convener of the Gas and Electric Lighting Committee of Aberdeen Town Council, attended at the Corporation electric station and formally turned steam on to the new 420-kw. Westinghouse generator, with Willans engine. The new generator, which is the largest installation that has yet been placed in the works at Aberdeen, is of 700 h.p., and has a capacity for lighting 20,000 lamps.

Appointments Vacant.—The Corporation of Lancaster invite applications for the appointment of an electrical engineer.—The Corporation of Grimsby invite applications for the post of assistant engineer in their electricity department.—A mains superintendent and a cable jointer are required by the City of York.—The Corporation of Perth require a resident electrical engineer. Particulars of these vacancies appear in our advertisement columns.

Cardiff.—Mr. Arthur Ellis, of Newcastle, whose appointment we announced some time ago as an electrical engineer and tramway manager, has now been elected by the joint committee of the Electric Lighting and New Tramways Committee sole engineer to the Electrical Committee, as well as electrical manager of the New Tramways Committee of the Corporation of Cardiff, at a salary of £750 per annum, to be increased £50 annually for five years.

Smoke Nuisance.—The Lambeth Council are again prosecuting the South London Electric Light Company for alleged smoke nuisance. As far as we can gather, there appears to be a decided conflict between the evidence of the Council's inspector and that adduced on behalf of the company. The case being still *sub judice*, we, of course, refrain from making any comments, and reserve ourselves to do so after the adjourned hearing on Wednesday next.

Share Market.—On Friday last electrics did not move, and very little was done except in debentures of all sorts. Tractions kept steady. Shares were steady on Saturday without change, and debentures were all in strong demand at the beginning of the week. Shares were unchanged, but fairly active. The feature in tractions was the demand for all Belgrano issues on the good traffics of late. Prices seemed inclined to harden on the following day, but there was little doing, and no particular changes have taken place since.

Monmouthshire.—At the adjourned conference of delegates of councils of the Monmouthshire Western Valleys, held at Abercarn on Monday, to consider the electric lighting scheme only Abercarn and Risca were represented. Letters were read stating that the Abertillery Council had decided not to share in the expense of an expert, and that Nantyglo and Blaina Council would take no action in the matter. It was agreed to recommend the Abercarn and Risca Councils to obtain expert evidence upon the desirability of providing a joint electrical installation.

Stoke-on-Trent.—Plans of the proposed new laundry and boiler-house at the workhouse have been approved. A loan of £14,900 had been applied for in respect of the erection of these buildings and of the proposed electric lighting installation. The Local Government Board, however, considered that of the sum in question £5,000 only might properly be repaid in 30 years, and that the remaining £9,900 should be repaid in a period not exceeding 15 years. It has now been decided to urge the Local Government Board to authorise the borrowing of the £9,900 for a period of 20 years.

Proposed New Bills.—The following is the concluded list of notices of intention to apply for Bills that have appeared in the *London Gazette*: Electric tramways and railways: Glossop (U.D.C.), Colchester (Corporation), Northampton (Corporation), Ashton-under-Lyne (Corporation), Denton (U.D.C.). Electric lighting: Lewisham and Penge (company), New Hunstanton (U.D.C.), Aspull (U.D.C.), Ashton-in-Makerfield (U.D.C.), Mountain Ash (U.D.C.), Briton Ferry (U.D.C.), Skipton (U.D.C.), Birstall (U.D.C.), Chesham (U.D.C.), Macclesfield (Corporation), Stratford-on-Avon (Corporation).

Digitized by Google

Selby.—The new workhouse was formally opened on Dec. 4. If it had not been for some delay in the electrical works the building could have been opened two months ago. The electric light is now completed, and the whole place is well lighted, the station is duplicated, and the accumulators are sufficient to avoid all chance of a breakdown.

At Last!—The Common Council have finally been moved to do a little to mitigate the nuisance caused by the uprooting of the London streets in order to lay telephone and telegraph wires. They have now decided that in future all work entailing interference with the public ways of the City should be carried on continuously day and night.

Harrow.—At the meeting of the Urban District Council last week the point of making good paths broken up by the electric light company was raised. The Chairman read a letter from the company, stating that they were willing to come to some arrangement as to reinstating the footpaths. It was agreed to refer the matter to the Surveyor's Committee.

Barry.—In addition to making application to Parliament for a provisional order of the Board of Trade for the establishment of electric lighting plant and supply in the town, the Barry Urban District Council are negotiating for the purchase of the railway siding at the rear of Thompson-street, Barry Dock, which they desire to utilise for the purposes of the electric station.

Sligo.—The Town Council appear to be favourably impressed with Mr. Enwright's proposal to apply to the Board of Trade for a provisional order for the public and private lighting by electricity of the town of Sligo. Mr. Enwright's intention is, with the consent of the Corporation, to get a company to carry out the work, and to make it a condition that the price should not exceed 6d. per unit for private lighting, and 4½d. for public lighting.

Sunbury.—At the last meeting of the District Council a letter was read from Edmundson's Electricity Corporation, whose application for a provisional order to supply electric light in the district the Council had decided to oppose, stating that as they had been unable to obtain the consent of other district councils in the neighbourhood they did not intend to proceed with their application for electric lighting powers this session. In the meantime they proposed to take steps for the construction of electric lighting works at Twickenham.

Hampstead.—The Borough Council have confirmed a resolution passed by the late Vestry to charge the electric lighting account with the sum of £12,500 in respect of the use of the whole of the existing stoneyard for the purposes of that department, and to appropriate such amount towards the cost of providing a new stoneyard. Statutory notices are to be given to the Hampstead Electric Supply Company, Limited, and the Electric Laundry Company, Limited, in respect of alleged infringements of the requirements of the Public Health (London) Act, 1891, as to smoke consumption.

Ilford.—The charge for all current supplied for motive power or heating purposes, through a separate meter, has been fixed at 8d. per unit for one hour's use per diem of the maximum demand, with a charge of 1d. per unit for all units used in excess of that number. The price of electrical energy supplied to places of worship is to be at the uniform rate of 5d. per unit, and the following charges will be made for the hire of meters, including the maximum demand indicator: 1s. per quarter up to 15 lights, 16 c.p.; 1s. 6d. 25 lights, 16 c.p; 2s. 50 lights, 16 c.p.; 2s. 6d. all above, or the equivalent.

Eccles.—Sanction has now been obtained to a loan of £5,306 to cover overspent capital on the electric lighting scheme. The borough electrical engineer is about to prepare a scheme for the extension of the electric light undertaking, with the view of the supply of electrical current for tramway purposes and the supply of the whole of the lamps in the borough. The Council will also apply for sanction to the borrowing of £515 for the provision and laying of additional cable for electric lighting purposes. The electrical engineer has been authorised to obtain the necessary gear for adjusting the speed of the engines, at a cost of £20 each engine.

Kensington.—The Guardians some time ago appointed a special committee to consider whether the workhouse, infirmary, and other premises should be lighted by electricity, and, if so, whether current should be taken from the public supply mains or generated at home. Acting on expert advice obtained from Prof. Robinson, the committee recommended a self-contained installation estimated to cost £12,500. This recommendation came up for discussion at the last meeting of the Guardians, but it was decided that the first thing to do was to supply each member with a copy of the professor's report. The committee's recommendation was accordingly postponed to allow time for the report to be circulated.

Dudley.—We understand that the business of Messrs. Whittaker Bros. has been transformed into a limited liability company under the style of Whittaker Bros., Limited This firm has obtained the contract from the Corporation for free wiring and fitting premises of the Corporation's customers. Free wiring must be giving the scheme great impetus seeing that Whittaker Bros., Limited, have fixed or are fixing about 10,000 lamps in shops, works, offices, residences, churches, and theatres, including the municipal buildings and the free library and science and art schools at Dudley and Kidderminster. They have also wired the new Temperance Institute, Mr. E. C. Theedam supplying the fittings.

Forthcoming Exhibition.—The Managing Committee of the International Exhibition of Fire-Extinguishing and Life-Saving Apparatus, to be held in Berlin during 1900, are able to publish a very satisfactory preliminary report, from which it appears a large number of home and foreign firms have already promised to contribute exhibits. The principal railway companies concerned are also giving their support by undertaking to return, carriage free, all exhibits which may remain unsold, while the Norddeutsche-Lloyd and the Hamburg-American lines, besides many other large steamship companies, offer to carry exhibits both to and from the exhibition free of charge. Further information may be obtained on application to the committee's offices, 41, Lindenstrasse, Berlin, S.W.

Russia. — The *Financial News* correspondent wires from St. Petersburg: "The results of the public tenders invited for the taking over of the telephone services in the cities of St. Petersburg, Moscow, Warsaw, Odessa, and Riga, where the concession of the Bell Company is shortly to expire, have just been made public, but are still awaiting the sanction of the Minister of the Interior. In St. Petersburg the municipality scored with an offer to fix the annual subscribers' fee at 55 roubles; at Moscow, the Swedish-Russian Telephone Company, with a subscription fee of 79 roubles; and at Warsaw another Swedish concern (the Sverddergren Company), with 69 roubles. At Odessa a Mr. Raffalovitsch proposed a price of 48 roubles, and at Riga the lowest tender was 57 roubles, offered by Messrs. Rukkert and Co."

Transvaal.—We have been favoured with a copy of the following proclamation which has just appeared in the *Johannesburg Gazette*: "V.R.—Imperial Government Municipality—Municipal Notice—Town Engineer's Department—Notice to Architects, Contractors, and others.—Notice is hereby given that the town engineer (Mr. Chas. Aburrow, M.I.C.E.) has returned to his duties, and can be seen by the public at office No. 14 of the Imperial Government Municipality, *Standard and Diggers' News* Buildings. The laws relating to buildings, etc., of the late Town Council remain in force, and special attention is hereby drawn to hoardings, fences, etc., on and adjoining public streets, which must be maintained in good order in accordance with the regulations.—W. A. J. O'Meara (Major), acting burgomaster, Johannesburg, Nov. 5, 1900."

Durham Power Scheme.—At the last meeting of the Tees Conservancy it was mentioned that an application was intended to be made in the ensuing session of Parliament for leave to bring in a Bill by the company to be known as the Cleveland and Durham Counties Electric Power Company. Amongst various purposes the company seek power to acquire compulsorily or by agreement easements or rights in or under the bed, foreshore, and channel of the River Tees, and also power to lay down and maintain under the bed, foreshore, and channel of the river electric cables. It is also intended to acquire a parcel of reclaimed land at Haverton Hill. The company is being incorporated for the purpose of establishing and carrying on electric works and for generating, producing, and supplying electric energy. The matter was referred to the Parliamentary Committee of the Conservancy.

Stepney.—At the last meeting of the Borough Council, a report by the Local Committee for Whitechapel was agreed to, which recommended that all the electric lamps in the Whitechapel area be kept alight all night for the advantage of the public; that a representation be made by the metropolitan borough of Stepney to the London County Council for the loan of £20,000 for Whitechapel electric lighting purposes, such loan having already been applied for from the London County Council by the late White chapel District Board of Works upon terms agreed upon, and such having already been taken by the London County Council with the view of making such allowance; that authority be given to the Whitechapel Electric Lighting Committee to expend by resolution for any one purpose a sum not exceeding £50; that authority be given to the Whitechapel General Purposes Committee to expend by resolution for any one purpose a sum not exceeding £50.

Swansea.—The electric lighting works are almost completed and ready for a start. Some time ago it was agreed to allow the wiring to be done by the National Free Wiring Company. The agreement was, however, a short time ago withdrawn, and at last week's meeting of the Electric Lighting Committee the Chairman advised that a new contract be entered into with the company. The company had asked 1s. 4d. per lamp per annum, while the Corporation held out for 1s., and as the company were now willing to accept the Corporation's offer he thought, in the interests of the station as well as of the possible consumers who could not afford or did not care to find the initial outlay, it was desirable that the agreement should be carried out. During the discussion it was pointed out that the company would be the landlords in perpetuity, and that it would be paid back the prime cost over and over again. When a customer had paid off the net value of the plant laid down, he should be entirely free in that respect. The Chairman said if the Corporation did the work it would probably decide on the adoption of similar terms to those of the company, but eventually it was decided to ask the company for terms more favourable to the consumers.

Montrose.—The Edmundson's Electricity Company, Limited, have given notice (in accordance with the provisions of the transfer deed of Montrose Electric Lighting Order, 1898, granted by the Board of Trade for the establishment of the electricity supply undertaking for the burgh) of their intention to lay down main cables and the boxes for connecting up same for supply to a number of thoroughfares named. The feeder mains would run from the works to the centres of the town, and were of a section large enough to allow of 5,000 lamps being supplied at once, and the distributing mains would also be of a capacity to supply that number of lamps. The cables would be laid direct in the ground,

Digitized by Google

no conduits of any sort being used; a tarred wood board or row of bricks would be laid above each as an indication of the presence of the cable, which would be laid under the footpath at an average depth of 10in., and under a roadway from 18in. to 24in. The work would be carried through very expeditiously, the special class of cables allowing this to be done, so as to avoid interfering with the convenience of the householders along the routes of work as little as possible. The feeder boxes to be put in at the points where the feeder cables joined the distributors would be cast iron pillar boxes set in the footways, and the boxes at the other points where the distributors met cast-iron boxes would be placed under the pavement in suitable pits with covers filled in with cement to match the pavement. The matter is now in the hands of the Streets and Roads Committee.

Southampton.—We notice that the Electricity Committee have received a number of claims with respect to accidents. Amongst these Mr. Joseph Morris claimed £25 in respect of alleged injuries sustained through an escape of electricity from one of the standards belonging to the Corporation in the High street, opposite the Capital and Counties Bank. The electrical engineer has reported that it was an impossibility for the column referred to to have been the cause of the alleged physical injuries. The committee decided to decline to admit any liability in the matter on the part of the Council. Mr. Howat, at present filling the position of third engineer, has been promoted to be second engineer, and Mr. H. A. Pearson has been appointed third engineer. The electrical engineer in his report last week stated that some trouble had lately been experienced with the joints in the high-tension cables, and the lighting in the upper part of the town had been affected thereby; that he had taken the matter up with Messrs. Glovers, who had remade the faulty joints at their own expense, although their guarantee had expired some time ago. The electrical engineer also reported that on two occasions the alternating current had been off for about 30 seconds owing to the breakdown of coils in the armature of the alternators; that the continuous-current plant was overloaded nightly, making it necessary to run about two volts below pressure for about three hours every evening; that this state of things could not be remedied until the new set was at work, and the delay in the erection of the plant was due to the non-delivery of the dynamo. The committee, in consequence, resolved to instruct the town clerk to inform the contractors, S. Z. de Ferranti, Limited, that the penalty clause of their contract would be strictly enforced. An enquiry is to be held with regard to the loan of £12,000.

New Issue.—Edmundson's Electricity Corporation are making an issue of 6 per cent. cumulative preference shares at ¼ premium. These shares will be preferential as to capital as well. The revenue of the company has steadily increased since its formation in 1897, and the last balance-sheet shows a profit of £17,260. To pay the dividend on the proposed issue will only require £6,000, so there is ample margin. This company retains an interest in the following local lighting companies as mentioned below, for whom central stations have been erected, and where work has been done to the following extent:

		8-c.p. lamp equivalents installed.		
	Works opened.	Jan. 1, 1899.	Nov. 1, 1899.	Nov. 1, 1900
Winchester	June, 1898	3,815	8,669	13,764
Folkestone	July, 1898	10,089	16,361	22,944
Salisbury	July, 1898	2,169	4,778	9,313
High Wycombe	Sept., 1898	1,730	6,461	15,550
Bromley, Kent	Dec., 1898	2,308	6,089	11,627
Chislehurst	Mar., 1899	—	3,327	4,412
Newmarket	Mar., 1899	—	4,010	6,278
Woolwich (reconstructed)	Mar., 1899	—	8,587	18,905
Ventnor	April, 1899	—	2,513	6,388
Alderley Edge	Aug. 1899	—	810	2,112
Guernsey	April, 1900	—	—	6,173

The net profits of the company, after payment of debenture interest, have been as follows: for the year ended March 31, 1898, £5,145; March 31, 1899, £11,268; March 31, 1900, £17,260. The income derived from electricity supply investments alone has been as follows: for the year ended March 31, 1898, nil; March 31, 1899, nil; March 31, 1900, £4,438; for the year ending March 31, 1901, the directors consider, from a careful calculation, that the income from this source alone will be not less than £8,500, while the sum required for payment of debenture interest and preference dividend during the same period will amount to about £6,900.

Finchley.—The Urban District Council on Monday discussed the electric lighting question. The Council have obtained a provisional order. Effect must be given to that order before 1902. The work is estimated to cost £30,000, but nothing can be decided until Alderman Swinburn's report has been received. The following letters were received and referred to the Highways Committee: (1) From the North Metropolitan Electrical Power Distribution Company: "With reference to your letter of the 7th and our reply of the 9th, as we have no desire to act otherwise than in friendly co operation with your Council in the matter of the electric supply, we will take no further action with the application for a provisional order in the coming session. We have no doubt whatever that our proposals, if carried out, would be in the interest of your district, and trust that a little later on you will afford us the opportunity of resuming negotiations. Owing to flaws which have developed in some small accessories used in the lamp columns, the arc lighting at Barnet has been unsatisfactory, but this is now being remedied, and soon after Christmas we trust it will be convenient for the members of your Council to visit the works there." (2) From Mr. W. M. Woods, director of the Finchley Electric Lighting Company, Limited: "I have gathered from the Press that the subject of the electric lighting at Finchley is to be under discussion to-night. In view of any statement which you may be making to the Council, I beg to remind you of the proposals that I laid before your committee in the early part of this year. The generating station then referred to is approaching completion, and I am directed to inform you that this company is prepared to enter into negotiations with the District Council for providing a more extended system of lighting, either (*a*) on the basis of the Council providing and laying mains, and the company supplying and distributing the electric energy; or (*b*) on the basis of the company taking over either in part or wholly the powers obtained by the District Council under their provisional order. Probably some arrangements might be made to hand over to the Council for the benefit of the ratepayers a certain proportion of the net profits after providing a fair dividend on the capital invested. In the event of any terms being arranged, this company is prepared forthwith to put down plant capable of dealing with any demand that may arise and to provide further extensions as and when necessary. I shall be glad to attend before the Council if desired, and give any further information that may be required."

Fulham.—At Wednesday's meeting the Consulting Engineer submitted the following report: "Since the date of my last report to you, I have not much to say with regard to progress of work. Messrs. the General Electric Company have been pushing forward far more expeditiously than recently with the pipework, and I am glad to be able to report to you that this is now very nearly all completed. The Horsfall Destructor Company have now delivered the two remaining 6in. junction valves for the boilers, and this will enable the General Electric Company to complete the main steam ring in the boiler house. I hope to make the requisite tests of the whole of the pipework this week, and to have steam on some of the engines towards the end of the week, or the beginning of next. The switchboard connections in the station are not yet completed, and there are other minor matters that the General Electric Company have still to attend to. The work on the mains is not progressing fast enough. The Horsfall Company have, as above reported, delivered the two remaining valves for the boilers, but, with this exception, have made little progress with the work covered by their contract since the date of my last report to you. Their contract however, is, with few exceptions, practically complete. I am of opinion that work on the boundary walls and the gateways at the entrances to the site should be proceeded with expeditiously now. This work has, I understand, been placed in Mr. Botterill's hands, together with the roadways on the site." The Resident Engineer reported that since the last meeting of the committee applications equivalent to 263 8 c.p. lamps had been received, bringing the total applications (88 in number) to the equivalent of 8,933 8-c.p. lamps. The resident engineer has been authorised to expend a sum not exceeding £10 in purchasing necessary materials to commence the trial running of the engines, and he has been asked to report as to the cost of introducing the system of electric motor traction for the cartage of dust and trade refuse, and to prepare plans and specification for wiring the central library for electric light with a view to tenders for the work being obtained. A sub-committee of the Council recently had a conference with the committee of the Guardians, and placed before them the advantages which must accrue to the parish at large by the Guardians taking the electric current required from the Council's mains instead of erecting their own installation. It was suggested to charge the Guardians 3½d. per unit—*i.e.*, 25 per cent. discount—for 50,000 units per annum, subject to a proper agreement being entered into.

Heywood.—Mr. E. A. Sandford Fawcett held an enquiry last week into the application of the Town Council for sanction to borrow £17,000 for electric light purposes, and £5,438 for the erection of a refuse destructor. From the evidence given we gather that the canvass of the district resulted as follows: circulars sent out, 125; replies received, 93; number in affirmative, 58; number in negative, 23; number undecided, 12; number requiring power, 7; number of 8-c.p. lamps required, 106; number of 16 c.p. lamps required, 966—equal to 2,037 8-c.p. lights; power, 30¾ b.h.p.; affirmative replies which state no particulars, 10. Mr. W. P. Adams, the consulting electrical engineer, stated that it is proposed to lay the mains along all the compulsory area, and also along Manchester-road, to include Hopwood, on the three-wire, low-tension, continuous-current system with 400 volts between the outers. Consumers would be supplied at 200 volts. The total length of mains proposed to be laid was about 5,000 yards. From the results of the canvass, adding 20 per cent. to the replies received which was what could be expected judging by experience, he estimated that during the first year the consumption would be 2,844 8-c.p. lights and 37 b.h.p. in motors. The income from this source would be £912. 9s.; from the sale of current for motors, £289. 1s. 3d.; and for meter rents, etc., £50; a total of £1,251. 10s. 3d. The estimated expenditure amounted to £778. 11s. 10d., leaving a balance of £472. 18s. 5d. Interest at 3 per cent. on £15,000 would absorb £450, and there would be a surplus of £22. 18s. 5d. This surplus was small, and it was desirable that the Board should sanction the deferment of payments on sinking funds until the fourth year, as had been done in other towns. Dealing with the plant, Mr. Adams said that two steam generators, two boilers capable of evaporating 3,000lb. of water per hour each, and two batteries of 115 cells each would be required. The distributing mains would be laid on the solid system. The boiler-house plant was estimated to cost £2,728. 8s. 6d.; engine-room plant, £2,074; battery-room plant, £869; switchboard

Digitized by Google

and connections, £762; station lighting, £116; feeders and mains, £1,597. 16s. 9d.; meters, £242. 10s.; laying cables conduits, house connections, etc., £1,342 10s.—a total of £9,732. 5s. 1d. The amount of the buildings was £4,557. 12s. 7d.; contingencies and engineering expenses, £691. 0s. 3d—a total of £14 980. 17s. 11d. The sum of £2 000 was to be borrowed to defray the cost of wiring consumers' premises. This would be done on the deferred payment system, carrying the repayments over five years. The Inspector was afraid that this was hardly subject for a loan; still, it was a matter for the Board. Mr. J. Ainsworth Settle, the borough engineer, stated that the works in progress commenced in July under three contracts—one for the electrical works proper, amounting to £3,002. 6s. 1d.; a second one for the roof, amounting to £130; and a third for the chimney, amounting to £692. 10s. Other expenses, amounting to £67 6s. 6d., had been incurred on another site in Hind Hill-street, which was first fixed upon as the site of the works, but was found to be unsuitable. With regard to the refuse destructor, it was stated that the Council received sanction to erect a destructor and authority to borrow £3,000 in 1893, but the destructor had not been erected before now, partly on account of difficulties connected with the site. The borough engineer said it was now proposed to erect a two-cell destructor on Meldrum's principle It would destroy from 25 to 30 tons per day.

PROVISIONAL PATENTS, 1900.

NOVEMBER 26.

21336. An improved illuminated advertising device for attachment to incandescent electric lamps and the like. Leo Connor, 34, Castle-street, Liverpool.

21366. An improved method of and means for joining the ends of lengths of telegraph wires and other wires. Richard James Fawcett, 322, High Holborn, London.

21374. Improvements relating to electric incandescent lamps. Henry Harris Lake, 45 Southampton-buildings, Chancery-lane, London. (The firm Electrische Glühlampen-Fabrik "Watt" Scharf und Co., Austria.)

21390. Improvements in variable resistance electric contacts. Francis Greenwich Sharp, 24, Southampton-buildings, Chancery lane, London.

NOVEMBER 27.

21409. Improvements in conduits for electrical conductors. Sydney Bryan Donkin, 5, St. Loo mansions, Chelsea, London.

21429. Improvements in or relating to dynamometers Karl Leverkus, 21, Pestalozzistrasse, Charlottenburg, Germany.

21447. Improvements in electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Granville T. Woods, United States.) (Complete specification.)

21448. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States) (Complete specification.)

21449. Improvements in interrupting devices for electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edwin W. Rice, jun., United States) (Complete specification.)

21450. Improvements in methods of transforming alternating electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Jonathan E. Woodbridge, United States.) (Complete specification)

21457. Improvements in telephony and telegraphy. Sidney George Brown, 9, Putney-hill, Putney, London.

21459. Improvements in safety cut-outs for electric circuits. Joseph Sachs, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21469. Improvements in lightning arresters for safety cut outs for electric circuits. Joseph Sachs, 23, Southampton-buildings, Chancery-lane, London (Complete specification.)

21478. Improvements in or relating to electric meters. John Henry Barker and James Alfred Ewing, 111, Hatton-garden, London.

21486. An improved appliance suitable for removing screw-threaded clamping rings from electric incandescent lampholders. Herbert Frank Cotton, Arthur Tennent Cotton, and Alfred Henry Reddell, 46, Lincoln's-inn-fields, London. (Complete specification.)

21490 Improvements relating to switches for use in electric circuits. Rudolf Lehnhoff 27, Chancery-lane, London.

NOVEMBER 28.

21497. Improvements relating to an electrolytic process and apparatus for the treatment of metalliferous ores and substances for the extraction of precious metals therefrom. George Harrison, of the firm of D. Young and Co., 11, Southampton buildings, Chancery-lane, London. (Alfred Charles Lorenz, United States.)

21501. Improvements in electrical switches. Alfred Watson, 180, Hockley-street, Birmingham.

21517. Improvements in electric belts. Otto Reinicke, 160, Friedrichstrasse, Berlin.

21533. Improvements in electrolytical apparatus. Joseph Matthews and William Davies, 77, Colmore row, Birmingham.

21538. Improvements in or relating to plates for electric batteries or the like. Alfred Julius Boult, 111, Hatton-garden, London. (William James Jackson, United States.) (Complete specification.)

21540. Improvements in or relating to overhead trolley wires or conductors for electric traction, overhead electric cables, or the like. Augustus Wyvill Hancock, John Leighton, and Robert Hacking, 111, Hatton-garden, London.

21566 Improvements in accumulators or secondary batteries. Carl Auer von Welsbach, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

21575 Improvements in electric telegraphs. Alexander Muirhead, 323, High Holborn, London.

NOVEMBER 29.

21578. Enclosed switch and cut-out combined. Walter John Fryer, 42, Sloane-square, London.

21615. Improvements in the socket joints of metallic telegraph and like poles. Edward Haward Chambers, 7, Staple-inn, London.

21617. Improvements in electrical fuse distribution or switch-boards. Conrad Edward Zimdars, 52, Chancery-lane, London.

21629. Improvements in and connected with means for the conversion of electrical energy derived from a source of direct current into varying or alternating currents. William Du Bois Duddell, 1, Queen Victoria-street, London.

21642. Improvements relating to electric fuses. John Charles Augustus Ward, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21644 Improvements in systems of electrical distribution. Henry Russell Kent, Westinghouse-buildings, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, May 1, 1900, being date of application in United States.)

21645. Improvements in and relating to electric switches. Clarke, Chapman, and Co., Limited and Alfred Lindsay Forster, 46, Lincoln's-inn-fields, London. (Complete specification.)

NOVEMBER 30.

21669. An improved reflector for electric or other lights. Samuel Hall, 4, St. Ann's-square, Manchester.

21674. Improvements in the method of supporting electric motors directly connected to the axles of cars or locomotives for electric railways or tramways. James Campbell, Arthur Hird, and Alexander Bewicke Blackburn, 17, Haymarket, Sheffield.

21700. Improvements in telephony. Louis Sterne, Donington House, Norfolk-street, Strand, London. (Samuel B. Fowler, United States.) (Complete specification.)

21701. Improvements in telephony. Louis Sterne, Donington House, Norfolk-street, Strand, London. (Samuel B. Fowler, United States.) (Complete specification.)

21702. Improvements in operating dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon street, London. (William Le R. Emmet, United States.) (Complete specification.)

21703. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon street, London. (Richard Fleming, United States.) (Complete specification.)

21704. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Ernst J. Berg, United States.) (Complete specification.)

21716. Improvements in and in the arrangement and construction of arc lamps. Charles Oliver, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

21722. Improvements in or relating to trolley wire and other conductors for electric traction. George Edward Heyldia, 6, Lord-street, Liverpool.

21732. Method of automatically cutting out main conductors of powerful electrical currents. Siemens Bros. and Co., Limited, Birkbeck Bank chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktiengesellschaft, Germany.) (Complete specification.)

21736. Improvements in apparatus for electrically lighting railway trains. Arthur Bernard Gill, 77, Chancery-lane, London.

21749 Improvements in dynamo-electric machines. Walter Langdon-Davies and Alfred Soames, 24, Southampton-buildings, Chancery-lane, London.

DECEMBER 1.

21759. An improved process for the electro-deposition of metals. Sherard Cowper-Coles, 82, Victoria-street, Westminster, London.

21804. Improvements in the manufacture of electrical insulating materials. Ernest Alexander Claremont, 4, Bloomsbury-square, London.

Digitized by Google

21306. Improvements in or relating to trolleys, switches, and crossings used in connection with overhead wires for electric traction Phelan McCulloch, 6, Lord-street, Liverpool.

21312. Improvements in and relating to electric arc lamps. Louis Warren Emerick, 77, Chancery-lane, London. (Complete specification.)

21315. Improvements in and relating to armatures and inductors. Victor Isodore Feeny, 60, Queen Victoria-street, London. (Allgemeine Elektricitäts-Gesellschaft, Germany.) Complete specification.)

21327. Improvements relating to electric incandescent lamps and the like. Societa Edison per la Fabricazione delle Lampade Eng. C. Clerici ed Co., 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, June 16, 1900, being date of application in Italy.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Dec. 22.

1899.

19539. Automatic electric circuit breakers for automatically closing the circuit after breaking. Hopkinson and Talbot.

23734. Electric lighting or heating apparatus. Bouillet.

24049. Intercommunication telephone systems. Wilson.

24053. Means for carrying off the gases generated in electrolytic apparatus. Bein.

25396. Electrically-propelled vehicles and permanent way therefor. Burnaby.

25417. Electromagnets. Delaveau

25421. Alternating-current generators Lamme. (Date applied for under International Convention, May 24, 1899.)

25439. Electrical contact apparatus for automatic signalling. Cadet and Chevallier.

25622. Method of fitting the covers of electric light fittings to their base parts. Lundberg and Lundberg.

1900.

1756. Suspension devices for arc lamps and the like. Wehrmann and Bastians.

2231. Telephone ear instrument holders. Stamp.

14054. Indicators for electric bells and the like. Julius Sax and Co. Limited, and Aird.

14798. Attachment to ceiling roses for raising and lowering central hole weights or fixing electrical fittings. Braham.

16248. Electric wall or floor coupling sockets. Davies, Kent, and Stewart.

17663. Method of and apparatus for signalling between stations having no electrical or mechanical connection. Silkman, Selden, and Day.

18347. Switch apparatus for electrically-propelled vehicles. Feeny. (Allgemeine Elektricitäts-Gesellschaft.)

18718. Magneto-electric ignition devices for explosion engines Seck.

NOTES.

Wireless Telegraphy.—Colonel Hozier, on behalf of Lloyd's Committee, on Saturday last notified Glasgow shipowners that it had been decided to establish experimentally the reporting of vessels by ætheric signalling at Inishtrahull, North of Ireland. It is expected that the installation will be ready by the middle of January. Arrangements are also being made for night signalling, as well as day, at Kildonan, Arran, Scotland.

Telephone Insulators. — According to the *Amur Gazette*, an extraordinary telephone line has been built by the Amur Goldworks Company at their place on the Seja River, to another establishment on the River Aldan. Instead of insulators, which are difficult to obtain in Siberia, empty bottles have been used on which to support the line. Anyone who is conversant with the characteristics of the Russians can quite believe that there was an ample supply of empty bottles in the district.

The Haab Electromagnet.—At a recent meeting of the Liverpool Medical Institution the electromagnet designed by Prof. Haab, of Zürich, for removing small fragments of iron and steel from the eye was described. Various speakers gave instances of the success of this magnet, which we have referred to previously in our columns. It requires about 1½ kw. to energise it, and is capable of lifting about half a ton. One can hardly wonder therefore that it has been successful in removing a great number of splinters of iron and steel from the interiors of patients' eyes.

Branch Line Service.—In view of the remarks of Prof. Carus-Wilson at the Institution of Electrical Engineers last week, in which he advocated increased service of lighter trains on branch lines of railways, it will be of interest to note that in Italy the Adriatic Railway Company is experimenting with a new and special type of automobile designed for use on rails. Each vehicle can carry 12 persons, and they will be used for conveying passengers in districts containing a number of towns at no great distance apart. By this means it is hoped to provide a fast service in districts where it would not pay to increase the number of heavy trains.

Railway Carriage Lighting.—Dr. Andrew Wilson, in the *Daily Chronicle* science columns, deals with the lighting of railway carriages by acetylene, which is stated to be so successful in Germany. Referring to the progress made in the United Kingdom, he has a good word to say for electric lighting in this connection. Thus he states that even in the North of Ireland he has found railway carriages with an electric lamp in each corner of each compartment, such as you can switch off and on as you will. There are very few lines now in England which have not adopted electricity as the illuminating agent in their new rolling-stock, and we are pleased because electric lamps are to be noticed in even the suburban trains on several London railways.

Cables to the West Indies.—In view of the fact that the contract between the West Indian Colonies and the Pacific Telegraph Company expires at the end of next year, a movement is on foot which it is hoped will result in the securing of improved connection between these colonies and Great Britain. The Governor of British Guiana is taking the move in the question, and has written to the governors of all the other colonies on the subject. It is urged that united action should be taken towards inducing the Imperial Government to organise an all-British cable out to the West Indies. Unfortunately, the colonies in question are by no means in the most prosperous condition owing to the depreciation of the sugar plantations, but we trust that something may be done in the direction indicated.

Metropolitan Railway Ventilation. — Mr. J. Galloway Weir, M.P., has been concerning himself over the ventilation of the Metropolitan and the District underground railways, and has secured copies of the correspondence on the matter between the companies and the Board of Trade. The letters show that the introduction of the ventilating outlets recommended by the Parliamentary Committee is being postponed, due to the proposed adoption of electric traction. We presume that the authorised expense of constructing these ventilators will eventually be saved. It may be of interest to our readers to know that the member of Parliament above mentioned takes much interest in many things. It was of him that a colleague wrote :

> The weary Weir with questions drear
> The notice paper crams,
> Surely there never was a weir
> That caused so many dams.

The Glasgow Exhibition.—While the Glasgow Exhibition may only serve as an additional attraction, the fact remains that the city of Glasgow is selected as the meeting place of a great number of engineering institutions during the next year. Thus the Institution of Civil Engineers are holding a congress in the city; the annual meeting of the Municipal Electrical Association is also to be held there; and we now learn that the Automobile Club have so arranged their long-distance trials for 1901 that seven days will be spent at the Glasgow Exhibition. The route selected for the next year's trials will comprise 1,200 miles. This long journey will be commenced on Aug. 12, and the cars are due at Glasgow on Aug. 19. The cars will be on view in the exhibition for the next five days, and the return journey commenced on the 26th. We understand that the buildings of the exhibition are now almost completed, and that good support is being obtained from all the leading engineering firms in the country.

The Proposed Mont Blanc Railway.—The special correspondent, as a rule, is lacking in humour, and the special correspondent at Geneva of the *Daily Mail* is no exception. This gentleman states that "the construction of a railway to the summit of Mont Blanc, similar in all respects to the Jungfrau line, is under consideration. The route which presents the least obstacles, and which is likely to be chosen, is on the Savoy side, departing from the village of Houches. There will be 12 stations, which will be specially built to resist the climatic conditions, and will be supplied with every convenience for travellers. The length of the mountain railway is estimated at 11 miles. The hydraulic power, which will be electricity, will be obtained from the River Arve and the Mer de Glace. The author of the scheme, a French engineer named Fabre, has laid the plans of the new railway before the French Minister of the Interior." If the line is not to be similar in all respects to the Jungfrau Railway, it might be an advantage to make the hydraulic power of gold instead of electricity.

The Central London Vibrations.—The numerous letters which have been written to the daily papers respecting the annoyance caused by the Central London Railway to householders along the line of route should be received with caution. It is exceedingly easy to write to the papers, and it is also easy to make the most of inconvenience, however slight. It will be noticed, however, that the Central London Company has not denied that their trains may be heard and a certain amount of vibration produced along certain parts of the line, and it will

Digitized by Google

be exceedingly interesting to hear the result of an expert examination about the point in question. What we should like to see would be a comparison made between the vibrations caused by the trains in the Central London Railway and by the traffic in the public streets. Another ill effect of the twopenny tube is exploited by the *Daily Mail*, and if sufficiently boomed will do much to increase the financial prosperity of the company. It is seriously stated by a passenger on the line that a journey on it produced on him the effect of intoxication. He had, in fact, after going out into the fresh air, to support himself by holding on to railings for 20 minutes. We think this gentleman had a remarkably cheap experience for his money.

Standard Time.—From the first of the new century we understand that the official standard time in Spain will be obtained from Greenwich, so that there will be absolute uniformity in time between Great Britain and Spain. Owing to the geographical position of the two countries, the error introduced between the official standard time and the local mean time for any part of Spain will not be very great, and there will be considerable advantage from the adoption of the Greenwich standard. This move raises the question as to whether it would not be advantageous for all nations to have a standard time. As far as those firms which have business over the submarine cables are concerned there would be considerable benefit derived, and it would also greatly help the numerous newspaper editors in preparing their foreign news. These advantages, we are afraid, will not be apparent to the great bulk of the people in the country, and the workman who has been used to dine at 12 noon would seriously object to an alteration which he would presume to have been made in his routine. We do not suppose that the official adoption of a standard time would produce riots similar to those known as the ten-day riots, but we are quite sure that no official standard would become common in the various countries, owing to the extremely radical changes which would have to be made.

Patents for Details.—We have several times had to refer to the patents which the two or three large manufacturing firms of the United States have taken out in this country for the details of their apparatus. These patents are, as a rule, for such trivial points in the device of the machinery as would be devised by the ordinary draughtsman, and which do not require any inventive skill. We have said before now that in our opinion these patents for details would not stand the test of the law courts. We are pleased to see that in the United States an action has recently been tried on this very point, and that our opinion has been upheld by the Court. The action in question was between the Thomson-Houston Electric Company and the Walker Company. The patent alleged to have been infringed by the defendants was for a brush-holder of the block form, in which a spring keeps the brush against the commutator. The brush moves in the slot or socket of the brush-holder. Another patent for an exceedingly common form of brush-holder was alleged to have been infringed, but the Court held that in each case the device which was patented was wholly wanting in novelty. We trust, therefore, that electrical engineers in England will not be frightened by the exceedingly numerous patents which these firms have taken out for details.

Electric Lighting in Bombay.—After years of consideration, a committee of the Bombay Corporation has at last recommended that an electric lighting concession should be granted. It is not convenient at this distance from the town to take up the question as to whether the supply could be most economically given by the Corporation or by a company. The only evidence we have is that the Corporation has refrained up to the present from taking any steps towards supplying electric light from a municipal station. On the other hand, the company to whom it is proposed by the Electric Lighting Committee to give the concession, have taken active steps in other parts of India for providing electric lighting for towns. As this company are the agents for Messrs. Crompton and Co., one can well believe that a certain amount of the energy of Lieutenant-Colonel Crompton has been infused into them. We therefore hope that there will no great delay over the granting of the concession, and that Messrs. Kilburn and Co. will carry out the work with their usual promptitude. As an example of what this company has done elsewhere, we may mention that the Calcutta Electric Supply Corporation have already declared a dividend, it being at the rate of 3 per cent. per annum for the half-year ending June 30. In view of the supply having only been given for a short time in Calcutta, this result is most satisfactory.

Smoke Nuisance.—An interesting case illustrating the law with respect to smoke nuisance was recently tried in the Lancashire Chancery Court. A new section of the line for the Midland Railway Company was, in the spring, being constructed at Heaton Mersey, and the plaintiff objected to the smoke issuing from the locomotives, etc., of the railway contractor. He urged that this smoke was greatly to his annoyance, and that it damaged the plants and shrubs in his garden. He particularly urged that orchids valued at £10,000 were liable to serious damage. The Vice-Chancellor ruled that a casual or temporary nuisance would not be interfered with, but that the Court would move in the matter if it were proved that substantial injury would be caused unless the nuisance complained of was stopped. The orchids, however, were not to be considered in the case, but only the effect of the smoke on ordinary garden plants. The decision of the Vice-Chancellor was that the smoke nuisance caused would have done damage to the garden, and that in consequence the verdict would be for the plaintiff, who would have the right to apply for an injunction if the nuisance were repeated. It seems to us to be rather a hard condition to lay down that contractors who have to work with temporary plant should be obliged to adopt smoke-consuming devices. Of course the actual damage done should be compensated for, but too much obstruction should not be placed in the way of conducting new transport facilities.

Institution of Electrical Engineers.—At the ordinary meeting of this Institution to be held on Thursday, the 20th inst., Lieut.-Colonel Crompton, E.R.E., will read a paper on the Electrical Engineers (Royal Engineers) Volunteers in South Africa. It is hoped that the lecture will be accompanied by lantern views illustrating the life of these volunteers at the front. We expect there will be a very large gathering to hear Lieut.-Colonel Crompton's experiences. It is obviously no sinecure to be the commanding officer of a corps of Electrical Engineers, and especially of a detachment just returned from the front. As an example of this we would instance the number of engagements at which Lieut.-Colonel Crompton has to speak within the next week. These commence with the dinner which is to be given at the Trocadero Restaurant on Saturday next by the members of the corps to the South African detachment. On Monday, the 17th, there will be another dinner to the detachment, at which again the commanding officer will have to speak, as will also be the case at the reception on Tuesday, the 18th, in the Covent Garden

Digitized by Google

Theatre. The lecture on Thursday should be practically the last straw, and we trust that Lieut.-Colonel Crompton will then have a rest till after the Christmas holidays. We understand that the applications for tickets for Covent Garden on the 18th are exceedingly numerous, and that great interest is being displayed in it by the ladies indirectly connected with the Institution.

Insulating Observatories.—The *Financial News* last week had a caustic leader on the question of the interference with magnetic observatories by stray currents from electric tramways. As far as the financial element in the leader is concerned, one cannot but agree with the remarks of the writer. It is a question of the ultimate good of the largest number, and we do not think that even a magnetic observatory should be allowed to interfere with improvements in facilities for rapid communication in large towns. We know that there has been a continuous record of magnetic observations carried out at the Kew Observatory for a large number of years, and that the sequence of these records will be broken if the observatory has to be moved elsewhere. It is, therefore, only to be expected that the physicists of the country should make strenuous efforts to protect the observatory. We believe that the electrical engineers responsible for the equipment of the lines near Kew have also undertaken to use special precautions against interfering with the instruments in the observatory. The decision as to whether these precautions are sufficient lies with the Board of Trade, and this decision is being held back unduly—in fact, the London United Tramways Company have practically everything ready for working, and yet the decision of the Board of Trade as to whether their system is to be allowed has not been given. Reverting to the leader in the *Financial News*, one finds that the writer has gone wrong in his scientific observations when he assumes that it is possible to insulate the instruments themselves against disturbances from stray currents from the tramways. Unfortunately, anything which would insulate these instruments from the magnetic lines of force from these stray currents would also insulate them from the field of the earth's magnetism.

High Vacua Testing.—A patent has recently been granted in the U.S.A. to Mr. John Waring for a method of gauging or measuring the degree of tension of a confined body of gas, and with especial reference to obtaining an equal vacuum in the exhaustion of electric lamps. The fundamental principle underlying the method is that the regular transmission of heat in a rarefied gaseous medium depends upon the density of that medium. In applying the invention a known resistance is taken as a standard, and with this is compared a resistance enclosed in a suitable chamber connected to the lamp bulbs or other chambers undergoing exhaustion. This comparison can best be made by using for the standard resistance one or more standard incandescent lamps and comparing therewith one or more similar lamps whose bulbs are in connection with the exhaust pipe to which the lamps are connected for exhaustion, a galvanometer being used to show the proper degree of vacuum. The theory of operation is that the deflection of the galvanometer is proportional to the change in resistance of the filament, which in turn is proportional to the change in temperature, and this in turn is proportional to the number of molecules impinging upon the filament, which number of molecules is proportional to the degree of vacuum; consequently, the deflection of the galvanometer is proportional to the vacuum. In other words, the method consists in electrically heating a conductor in a vacuum and measuring the electrical resistance of such conductor while heated. In carrying out the method a Wheatstone bridge arrangement is employed. We are indebted for the above to the *Electrical World*.

The Glasgow Section.—The section of the Institution of Electrical Engineers at Glasgow is infusing considerable vigour into its debates, and is also organising them on what we consider to be good lines. As an example of this, we may mention that on Wednesday last the discussion on the paper by Mr. W. E. Langdon on "The Supersession of the Steam by the Electric Locomotive" took place. The full debate will be reported in our next issue, and our readers will then see that the matter was taken up most thoroughly. This is due to one or two of the local members arranging for a sub-division of the various points raised, and selecting the most capable engineer in the district for each special point. As a contrast to this, the debate last week at the parent Institution is most striking. While certain speakers kept to the issues of the subject under discussion and added their practical experiences, there were others who simply wasted the time of the meeting. Without mentioning names, one is tempted to ask what value can possibly arise out of a *résumé* of the progress of telegraphy and the fight between electric lighting and gaslighting in a paper on the electrical equipment of our main lines of railway. Or, again, is it of interest to the members to know that the subject is an extremely old one, and that the speaker has looked into the matter for various authorities and Governments, if that speaker refrains from giving in a concise manner the conclusions which he came to from his investigations. In our opinion, it would be well to enforce a rule that no member should be allowed to continue speaking if he wastes three minutes over introductory remarks which do not concern the paper.

Electrical Work at Cardiff.—The question has now been decided at Cardiff as to what should be done with respect to the vacancy created by Mr. Appelbee leaving to take up a more responsible position at Ashton-under-Lyne. It will be remembered that the Tramway Committee have had for some months now the services of an expert electrical engineer, and that it is proposed to erect a separate generating station for the tramway system. It has now been decided by the Council that this gentleman (Mr. A. Ellis) shall also be responsible for the electric lighting of Cardiff. In our opinion there is much to be gained by the combination of the two posts, always provided that the work of the engineer selected is not hampered by conflicts between the two committees. In spite of what has been written by what may be termed interested engineers, there is practically very little advantage in isolating the tramway generating works from those wholly used for electric lighting. In the present instance the fact has to be considered that at Cardiff alternating currents are used for lighting, whereas, of course, the tramway machinery is likely to be of continuous current. There is no reason why the much needed extensions in the electric lighting system should not be carried out on the direct-current system, and in that case plant could well be placed in the same building as the tramway plant. If this is done, there will be a saving in the stand-by plant required, and also in the cost of labour. The only thing which seems likely to act against a combined scheme is the character which the councillors at Cardiff have for interfering with the under-officials of their departments. As, however, the Electric Lighting Committee have agreed to accept the electrical engineer of the Tramway Committee as quite capable of managing their electric lighting station, mains, and particularly the staff, they will, we hope, work smoothly with the Traction Committee. In view of the history of the Cardiff undertaking for the last three years, it is evident that the organisation of a staff interfered

Digitized by Google

with and mismanaged by the individual members of the committee has been a very heavy task for the engineer who is now leaving Cardiff. We congratulate Mr. Ellis on his appointment, and wish him every success in the heavy work he has in hand in equipping the tramways, etc.

The Government and Telephonic Facilities.—On Friday last an influential deputation waited upon the Marquis of Londonderry at the General Post Office to protest against the suggestion of the Post Office to cut off their special wires to Glasgow. It appears that some large firms arranged with the National Telephone Company to have special wires communicating with the telephone exchange in Glasgow, as there were too many delays by going on the public trunk wires. The Government took over the trunk from the National Telephone Company in 1896, and the Government contend that by the agreement with the National Telephone Company all the business should come on the trunk lines. The deputation pointed out that their agreements with the Telephone Company were made prior to the trunk wires being acquired by the Government; that the facilities given on the trunk lines were not such as would meet the demands of their business; and that the royalty paid by the deputation to the National Telephone Company would equal, if not exceed, any charges payable to the Government for the use of the trunk wires. The Marquis of Londonderry promised to consider the matter, and see whether any possible arrangement could be made to meet the difficulty. The real point at issue seems to be as to whether firms carrying on business at considerable distances from the large industrial centres are to be compelled to use the trunk wires, or whether the Government will not erect and maintain for them independent private lines. We do not think that it is so much the question of expense that these firms consider as the saving in time, and also the convenience of being able to at once call up the central exchange without the intervention of a local exchange. From what we remember of the Newcastle-on-Tyne Post Office telephone system some eight or ten years ago, its great advantage over the company's exchange was that most of the large collieries and ironworks in Northumberland as well as the large shipbuilding yards and dry docks were connected direct with this exchange. In consequence, one could quickly get through communication, involving only one switching operation. We trust, therefore, that the Marquis of Londonderry will not allow red-tape to prevent the establishment of long private lines in connection with telephone systems, whether they are managed by municipal authorities or by the National Telephone Company.

Railway Traction.—In a leading article the *Elektrotechnische Zeitschrift* comments on the increasing practicability of equipping standard-gauge railways for electric traction. Since considerable distances are involved by railway work, the transmission of energy by means of high-tension multiphase currents is a fundamental basis for such projects, opines the authority in question. But the transformation of the energy prior to its final conveyance to the propelling motors of the trains may be accomplished in various ways. As a matter of fact, three systems have already been tried. One of these consists in the conversion of the high-pressure multiphase currents into continuous currents of moderate pressure by means of fixed transformers and rotary converters placed in sub-stations. In this case the arrangements are similar to those prevailing for ordinary tramways, except that they are on a correspondingly larger scale. A second system consists in converting the high-pressure multiphase currents into multiphase currents of moderate pressure, and conveying the same to the trains through three separate conductors. In this case at least two special conductors are requisite, while the rails may constitute the third, and the trains would, of course, be equipped with multiphase motors. The third system consists in conducting the high-pressure multiphase currents by means of three overhead wires direct to the train, which is equipped with transformers and multiphase motors. As regards the relative values of the three systems, expert opinions differ. Each has its particular advantages and disadvantages. To the first-mentioned system belongs the merit of having the least number of untried combinations, besides that of being already extensively adopted. But as a set off against the great advantage of securing complete control of the speed and of obtaining high efficiency at all speeds when continuous-current motors are employed, the disadvantage of having to take fairly large currents from the working line must be taken into account. The same disadvantage holds for the second system, which does not, however, combine the easy regulation and high efficiency of the motors as a compensation, for which reason it has been adopted only where fairly constant speed can be maintained. The third system combines the great advantage of easy transmission, and, therefore, permits the use of heavy trains designed for high speeds, by virtue of which its application for standard-gauge railways gives great promise of success. Experiments in Lichterfelde have proved the practical possibility of this system, and a trial on a larger scale is to be made on the military railway to Zossen.

Road Traction.—Prof. Hele-Shaw's paper on "Road Traction" attracted a good attendance at the Society of Arts on the Wednesday of last week. The author's zeal in all that pertains to the improvement of road surface and to the perfection of automobiles is well known. In the paper in question a strong contrast was drawn between the ease with which resistance to motion in water can be ascertained and predetermined, as compared with the difficulty in arriving at any reliable average figures for road traction. Thus figures were quoted by the author to show that the maximum tractive effort on a good road may vary in the ratio of 1 to 3, according to the state of the weather. One most interesting point which was discussed in the paper is the wear of the road due to heavy automobiles passing over them. Figures are quoted from experimental trials in France to show that such heavy motors may increase the cost of upkeep of a road by as much as £50 per mile per annum. It does not, however, follow from this that these heavy motorcars should not be used, because, even considering the extra cost of upkeep of road, they may be considerably cheaper transport agents than horse-drawn vehicles or local railways. Prof. Hele-Shaw, however, hoped that the designers of carriages would so proportion the size of their tyres as to reduce the wear of the roads as much as possible. The instruments were described with which the committee appointed by the British Association are investigating the various causes of resistance to self-controlled vehicles on the common roads, and it was pointed out by the author that up to the present the frictional resistance of traction has not been separated out from the resistance due to vibrations of the vehicles. Another point requiring investigation was the influence in the power required, if any, of driving the car by the front or rear wheels respectively. In the discussion which followed, Lieut.-Colonel R. E. B. Crompton gave some interesting information as to the use of traction engines over the veldt in South Africa. In the months of July, August, and September the resistance to traction on the

Digitized by Google

surface of the veldt was less than occurred on the best English roads at this time of the year. In South Africa they had used for the first time very broad wheels, in absolute opposition to the time-honoured custom of the Boers, who employed only narrow wheels. The result of using the broader wheels was that the very thin crust of the veldt was not broken up, and that much greater traffic could be taken over a given route without destroying the surface. Mr. A. R. Sennet also spoke, and gave some curious figures with respect to the advantage of driving the front wheels of a carriage. These were not in the form in which they can be referred to as percentages, but of two exactly similar cabs, with the exception that one had the front wheels driven and the other the rear; the first-named was able to run for several hours more on the one charge of the accumulator. It is not easy to see why there should be any great difference between front and rear driving.

Incandescent Lamp Development.—Mr. Edwin W. Hammer is contributing to the *Electrical World* a series of articles on incandescent lamp development up to the year 1880. Those who are interested in historical lamps will find these articles of great value, in that illustrations are given as well as descriptions of most of the earlier forms of incandescent lamps. The author is chiefly indebted to the Patent Office records for some of his earlier information, and it is obvious, as he pointed out, that some of the earlier lamps could never have been successfully made by their inventors. For instance, the Starr-King lamp, which was patented in 1845 by an American, J. W. Starr, is one of these. It is generally believed that Mr. Starr resided in England. In this lamp two alternative forms were proposed. In one, wires of platinum or other metals were to be raised to incandescence, and in the other the inventor proposed to employ pieces of carbon. With respect to the carbon lamp, he states that the "form of carbon found on the interior of coal-gas retorts which have long been used is well suited for this purpose, and may be worked into the form of either small pencils or thin plates by the aid of the saw and file." The carbon plates or pencils are to be enclosed in a Torricellian vacuum produced in a glass tube similar to those used for barometers, except that the upper end is enlarged into a cylindrical bulb, with a stout platinum wire sealed in at the top. The length of the tube, exclusive of the bulb, was to be about 30in.; the tube is filled with mercury in the same manner as a barometer, and then stood upright with its open end in a basin of mercury, the column of mercury in the tube falling until it is balanced by atmospheric pressure, leaving a vacuum above it. The carbon rod produced by mechanical means was, of course, of very low resistance, and hence required a considerable current to heat it. It is curious to note that the other inventors, such as M. J. Roberts in 1852, Changz in 1853, Dr. Isaac Adams in 1865, Lodyguine in 1873, and Konn in 1875 all proposed to use this short thick bar of carbon of low resistance. It is due to this that the Edison-Swan combination were able to uphold as long as they did the patents for their incandescent lamps employing carbon filaments of high resistance. One of the most interesting lamps described in the first of Mr. Hammer's articles is the Konn lamp. In this there were a number of short rods of carbon, which were so arranged in connection with a falling switch that as soon as the first one had burnt out the next one came into circuit. Some extensive experiments carried out by this lamp showed that while the first carbon lasted somewhat more than a quarter of an hour, its average duration being 21 minutes, the succeeding carbons lasted on an average for two hours. It seemed from this that the vacuum employed was far from perfect, and that the small traces of oxygen remaining in the bulb were consumed by the burning up of the first filament.

Gloucestershire Engineering Society.—The first general meeting of the new session of the members of the Gloucestershire Engineering Society was held last week. There was a large attendance of members, the chair being taken by the recently-elected president, Mr. Hamilton Kilgour, A.M.I.C.E., M.I.E.E., electrical engineer for the borough of Cheltenham. In delivering his presidential address, Mr. Kilgour referred to the important industries which depended upon the application of electricity—namely: telegraphy—with and without wires, overland and sea and submarine, in peace and in war, simple, duplex, quadruplex, and multiplex, signalling, printing, and writing; telephony — urban and inter-urban; electric lighting—indoor and outdoor, mine lighting, searchlights in peace and in war; power transmission—to towns from a source of cheap power, to factories and in factories, electric tramways, electric railways; electro-chemistry—alkali and bleach manufacture, calcium carbide, typing, and sewage purification; and applications to medicine and surgery—galvanic treatment, cautery, and radiography. The revenue derived from these industries, and from those depending on the manufacture of machinery and apparatus for them, amounted to several millions per annum, and the total capital expenditure was expressed in hundreds of millions. These figures might enable them to realise the enormous part now played by electricity in contributing to the welfare of mankind, and might stimulate their interest in the labours of the pioneers of electrical science. There were at the present time, roughly speaking, 764,000 miles of telegraph lines, and a total mileage of conductors of 2,584,000 overhead. There were 85,000 miles of underground conductors, making a total of 2,669,000 miles of land conductors. Of the submarine cables, 20,357 miles belonged to various governments and 157,632 belonged to companies, making a total of 177,989 miles of submarine cables. There were 42 large cable ships kept for the repair of these cables. Turning to electric supply in Great Britain, there had been a total of £11,445,000 of capital expended by companies and £11,834,000 by municipalities, and at the same time revenues obtained from electric supply by companies of £1,053,000, and by municipalities of £988,000, or about £2,000,000 a year altogether. Those figures related simply to the United Kingdom. The number of lamps connected at the end of last year were 3,608,000 by companies and 4,052,000 by municipalities. With regard to telegraphs the number of messages sent last year amounted to 90,415,000. As to telephones, the National Telephone Company, the largest telephone company in the kingdom, had expended £6,827,000, and had paid a royalty to the Government in 1899 of £123,000. Those figures gave a fair idea of the enormous applications of electricity to the uses of their civilised life. Continuing, Mr. Kilgour dealt with some electrical discoveries that had been made in preceding centuries, and also with the progress in the science within the last 100 years. He said it was true that up till 1750 experiments were made, but it was practically only in the reign of the present Queen that English philosophers had made experiments which led to the discovery of electromagnetism. Nearly every great work that had been done had been effected in the reigns of the three Queens of England. Thus in Elizabeth's reign Gilbert made important discoveries in magnetism, and did some work in electricity. This was continued in Anne's reign by Haukabee, and in the present reign by such scientists as Faraday, Kelvin, Maxwell, and others.

THE ARRANGEMENT OF THE DISTRIBUTING NETWORK.

BY CHAS. A. GILLIN.

(Continued from page 799.)

Pursuing the method of dividing the network into sections, we can further facilitate the locating of faults by dividing each section into a number of sub-sections; and having traced the fault to a certain section, its sub-sections can be transferred one at a time to the main network without interrupting the supply in any way, and the section tested, as before, for the fault, each time a transfer takes place, the sub-section bearing the fault being thus easily found. In the same manner the streets forming the sub-section can be transferred to the main network one by one (as before without interrupting the supply) until the fault is located to a single length of cable, when the work of location is finished as far as the arrangement of the network is concerned.

In locating the fault in a section of the network as described above, the ingenious instrument devised by Mr. R. C. Quin, chief electrical engineer to the Corporation of Blackpool, which he calls a leakage ammeter, might be used with great advantage, as its employment would effect a considerable saving of time. Most of the time expended in the localisation of faults, however, is necessarily taken up in disconnecting and connecting up cables, etc., and before closing this article a few words may be said about the disconnecting boxes and their positions.

The Board of Trade regulations lay down the maximum number of consumers who may be affected by a breakdown as 80, and this implies that disconnecting boxes should be placed at a maximum distance of about a quarter of a mile apart in the streets of a town. This is a very convenient distance to place the boxes apart if there are no other long or important streets branching off the one in question, for, of course, boxes must be placed at all the principal street junctions, and, in fact, at almost every street where there is any prospect of a demand for electric energy. There is no necessity for fixing the disconnecting boxes until the time arrives for extending the mains down the streets referred to above, but provision for them should be made when laying the cables in such a manner that sufficient slack can be obtained for inserting the boxes without having to lengthen the cables.

Some illustrations are given to show the different types of disconnecting boxes in use at the present time in some of the larger supply undertakings. It will be noticed that to obtain access into most of these boxes, a number of screws have to be drawn, which operation takes up a good deal of time when a large number of boxes are being dealt with.

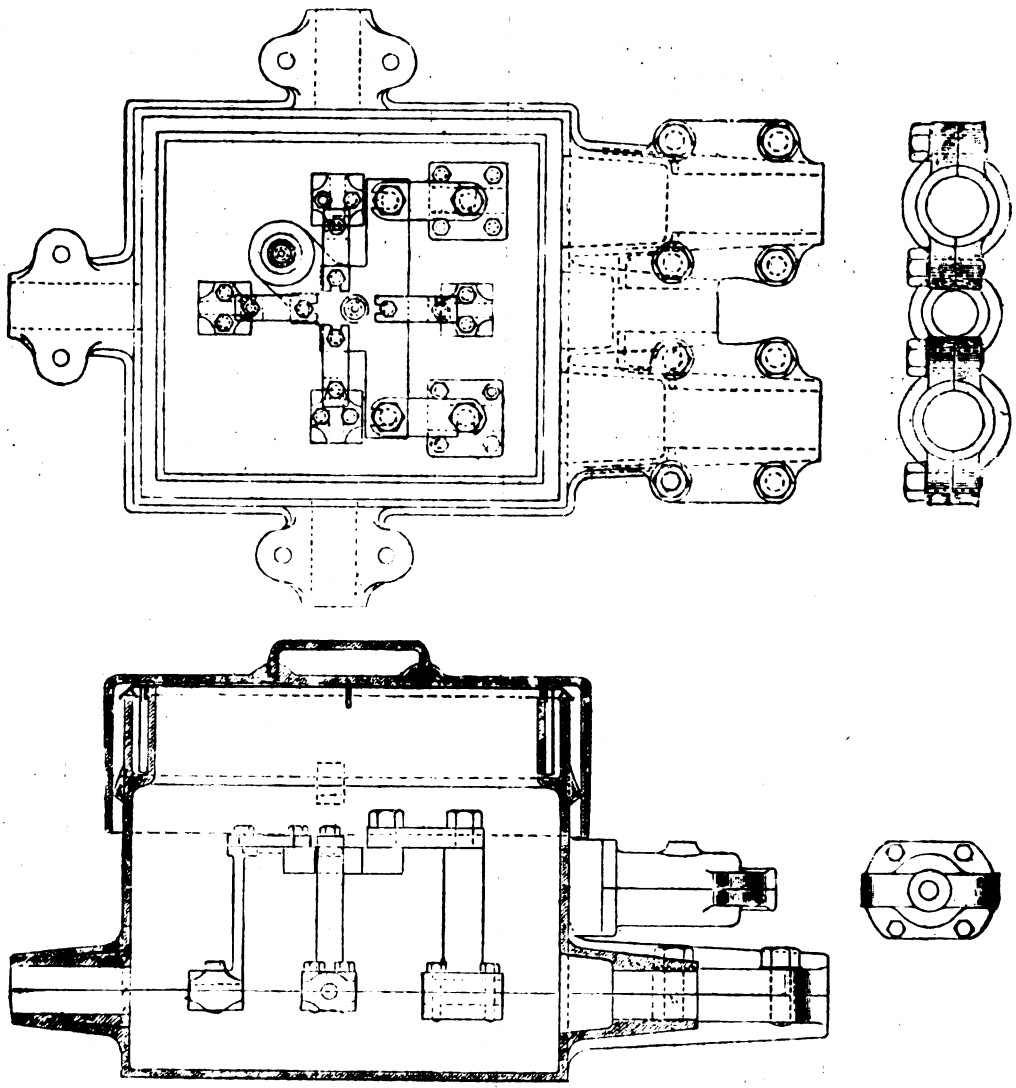

FIG. 6.

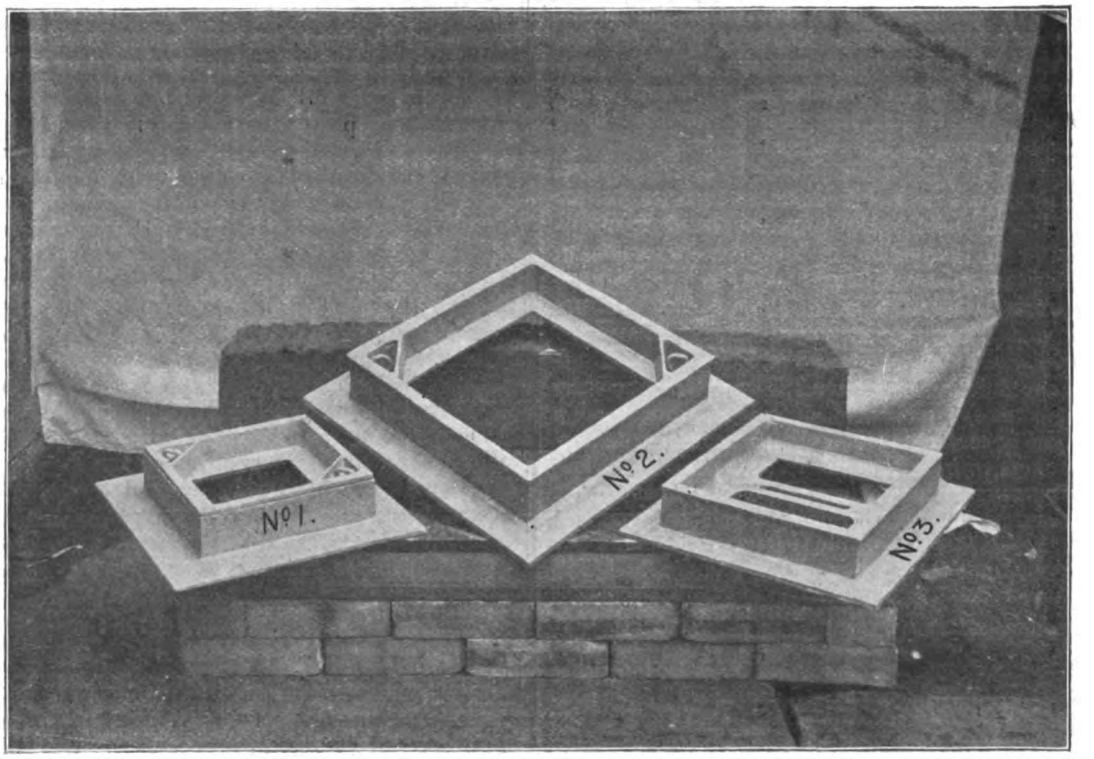
Most street boxes are rendered waterproof and air tight by means of indiarubber bands or rings inserted between the lid and the box—a most unsatisfactory method, as indiarubber perishes, sticks, and gives a lot of trouble generally. The arrangement of box cover shown in Figs. 6 and 7 was invented and patented in 1893 by Mr. S. W. Baynes, the present chief electrical engineer to the Vestry of St. Pancras, and it deserves particular notice in connection with the subject matter of this article as a great saver of time and labour, inasmuch as it takes less than one minute to open the box, disconnect, and close the box again, whereas in most other boxes the same cannot be done in 10 times that amount of time. It will be seen that there are no screws to unfasten, access being gained to the interior of the box by merely lifting off the covers. In designing the box cover so as to render the admission of water into the box impossible under any circumstances, the principle of the corollary to Boyle's law

Digitized by Google

was followed—*i.e.*, that the pressure of a given quantity of gas varies inversely as its volume. As shown in Fig. 6, the outer lid projects loosely over the outside of the box, and another lid made of copper fits into a trough containing oil, thus making the box air-tight. If water rises around the box and endeavours to force its way between the outer cover and the box, the enclosed air is compressed until its pressure balances the pressure of the water outside, and thus effectively prevents its ingress into the box. The depth of the cover can be increased so as to easily resist any depth of water, and the box may be filled with an insulating compound in the usual way, thus preventing any water finding its way in through the joints between the upper and lower parts of the box. Fig. 8 illustrates a box used by the Western Electric Company.

A few words may also be said here for the disconnecting fittings as a valuable factor in saving time. Complicated arrangements to save space and reduce the size of the disconnecting boxes should be rigorously avoided, as they tend not only to create confusion and loss of time, but often to cause disastrous results through taking off the wrong link, etc. Simplicity commends itself, and the



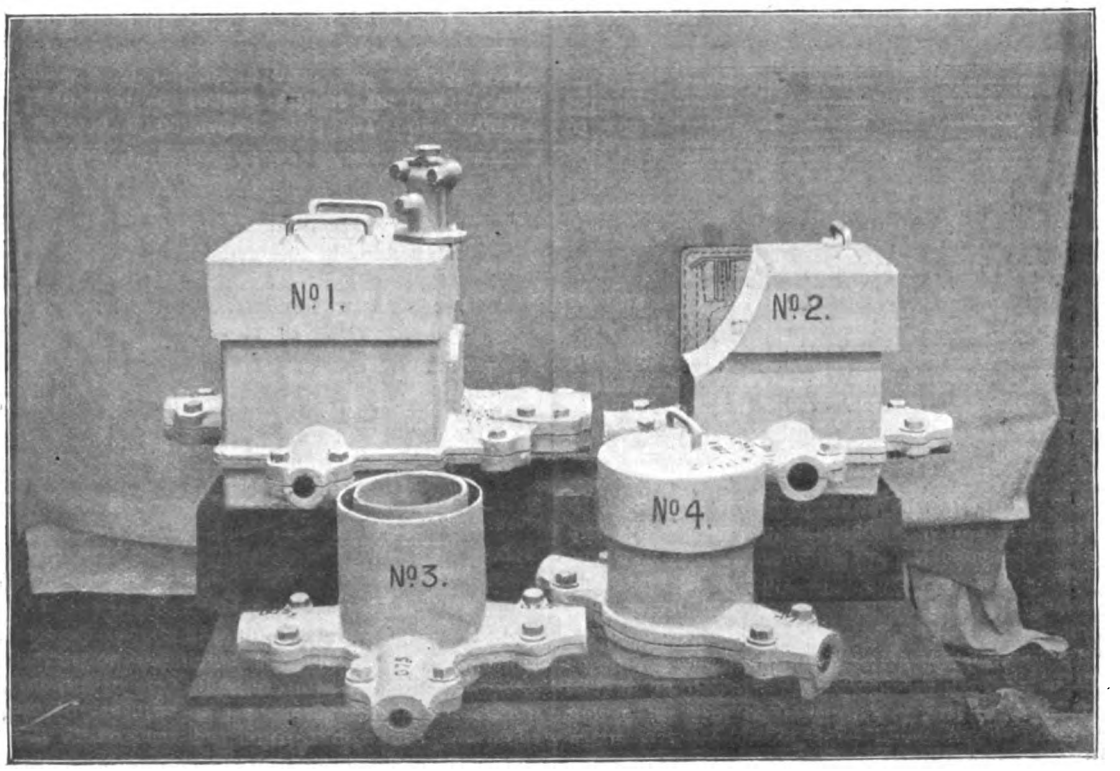


FIG. 7.

arrangement of disconnecting fittings in Fig. 6 may be pointed out as being exceedingly simple and reliable. This box was designed by the writer to serve the purpose of a feeding-box, provision being made for thickening up the feeders in the future. Four distributing cables leave the box to convey the current in four different directions, and the links for disconnecting them point respectively in the same direction as the distributors they disconnect, it

Digitized by Google

being quite unnecessary, therefore, to perform a feat of memory or make a trial disconnection before being able to cut off any desired cable. The same remarks apply to the feeder links.

In this article the writer has had no intention of criticising any existing systems of distribution, but he has endeavoured to indicate on broad lines a *system* of building up a distributing network from the commencement of the undertaking, so that all extensions of mains, however small, may be made subservient to the systematisation of the complete network. I have to thank Messrs. G. Clark and Sons, Shipley, the makers of the street boxes mentioned, and sole makers of Mr. Baynes's patent boxes, for

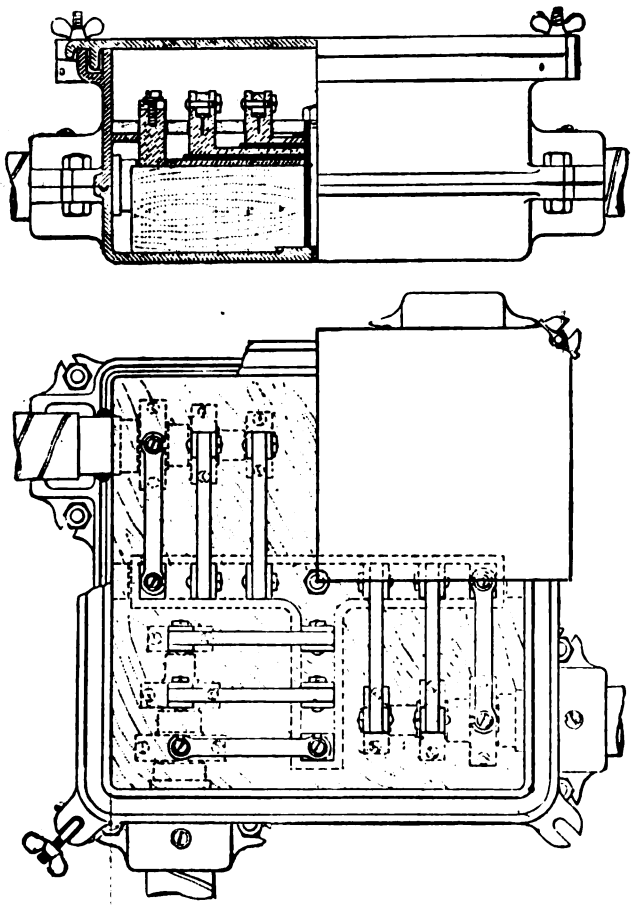

FIG. 8.

kindly lending me some of the illustrations used in this article, and taken from their catalogue.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

(Continued from page 764.)

THE MAGNETIC CIRCUIT.

If a coil of wire be wound in a helix so as to form a solenoid, the number of lines of force flowing through it will depend upon the magnetising force, or number of ampere-turns. Since in the C.G.S. system if H equal the magnetising force and $a\ t$ the number of ampere-turns, $H = \frac{4\pi}{10} \times \frac{a\ t}{e} = 1{\cdot}257$ times the ampere-turns per centimetre of length, the number of lines of force will be increased in the same proportion as is the magnetising force. If, however, a steel or iron core be inserted in the solenoid, we have seen that the number of lines of force now flowing through the core will be enormously increased, but they will be no longer increased proportionately with the increase in the number of the ampere-turns, although this will be the case when the magnetising force is weak, but as the number of ampere-turns is increased, they will have less effect in producing additional lines of force. We know that the reason why the number of lines of force is increased by the insertion of the iron core is because the iron offers them an easier path than air does, or, as it is usually termed, the permeability of iron is greater than that of air; and if we represent the induction or total number of lines of force flowing through unit cross-sectional area of the iron by B, for any given value of H, then $B = \mu H$, where μ is called the coefficient of permeability of the piece of iron. And it will be found that as B increases in value μ will decrease; or, in other words, as the iron becomes saturated its permeability becomes less.

Since $H = 1{\cdot}257 \times a\ t$, it is easy to measure the value of the magnetising force, and it is also not difficult to obtain values for B, although the method of doing so is outside the scope of these notes. If, then, a known number of turns of wire be wound round a given length of iron bent in the form of a closed ring, and the magnetising current be increased by uniform small amounts, and the different values of B and H marked on a chart—the former as ordinates and the latter as abscissæ—and the various points so obtained be joined together, we shall get the curve O A, shown in Fig. 28. If, now, the magnetising force be gradually withdrawn, the induction will decrease in value, but not as rapidly as it increased, and we shall obtain a curve, A B, where O A represents the amount of magnetism retained by the iron after all the magnetising force has been withdrawn. This value is called the residual magnetism of the iron. If, now, the direction of the current be reversed through the coil, the lines of force will flow in the opposite direction, and we shall obtain the curve B C, and it will be noticed that the curve crosses the axis H H at some little distance to the left of the axis B B showing that it requires a certain magnetising force in the opposite direction to get rid of the residual magnetism. If, finally, the magnetising force be again withdrawn, the induction will decrease, and we shall obtain the curve C D; and if the magnetising force be again applied, we shall get the curve D A, and additional cycles will approximately trace out the same curve.

This curve, D A B C, shown in Fig. 28, is of great value to all dynamo designers, and more especially the simple curve O A, or rather D A'. It will be noticed that a complete cycle gives a closed curve enclosing an area, and as the area enclosed by an engine indicator diagram shows the amount of work done by the engine in one cycle, so the area enclosed by this curve of magnetisation shows the amount of work done in magnetising a piece of iron first in one direction and then in another, and is of great assistance in calculating the watts lost in the armature, where in a bipolar dynamo the core undergoes this full cycle once every revolution.

Considering now the curve D A, we note that a small increase in the value of H causes a large increase in the value of B when H is only of small dimensions, but as H increases B does not increase so rapidly as at first, until at length the curve D A becomes almost a straight line, and the iron is said to be saturated.

We have seen from our fundamental equation that $E = \frac{\phi \times N \times C_a}{10^8 \times 60}$, and that both N and C_a are usually only of small dimensions, whilst ϕ is a number of large magnitude. There are two ways of securing a high value of ϕ: one is to make B of only moderate value, and the cross-sectional area of the yoke magnets and pole-pieces large; or to make B large and the sectional area smaller. Apart from other considerations, it will be found cheaper to make B of high value, for although a greater magnetising force, and consequently more copper wire, will be required in the field coils, yet the saving in iron will more than compensate for this.

There is, however, a much stronger reason why the value of B should be great. We have seen from Fig. 8 that the flow of the current through the armature, and the forward position of the brushes, creates, as it were, two bands of armature coils; one tending to give rise to the cross induction and the other to the back induction. These two sets of bands may be considered only as component parts of the magnetising force of the armature, and their resultant will lie in the line joining the two brushes, having its north and

Digitized by Google

south poles opposing the magnetising forces of the leading horns of the magnet poles. So that the resultant north pole of the armature will be opposite to the leading horn of the north field-magnet pole, and the south armature pole opposed to the leading horn of the south field-magnet pole. If B be of small value, the magnetic density per unit cross-sectional area of the field magnets and their pole-pieces will be low, and consequently the magnetic force in the leading horns will be small, or, as it is termed, the field is weak. Now we have already seen that if two like poles are brought opposite each other, they each try to induce a pole of the opposite polarity in the other, and if one is considerably stronger than the other, it will not only demagnetise, but may even reverse the polarity of the other. This is what will happen if the resultant poles of the armature are stronger than those of the leading horns. It has been shown that, in order to obtain sparkless commutation, the short-circuited coils must be under the influence of the field into which they are about to enter, and for this reason a forward lead is given to the brushes, and the short-circuited coils are brought almost under the tips of the leading horns; if, however, these have been demagnetised, the coils will not now be in the position for sparkless commutation, and an increased lead must be given to the brushes. Considering again the two bands of armature inductors separately, this increased lead will throw more coils into the band producing the back induction, and the field will be still further reduced and the number of active coils will be considerably reduced, so that the E.M.F. generated will not be nearly as great as it would were the lead of the brushes not so much. So that in order to try and obtain a position of sparkless commutation for the brushes with a weak field, the efficiency of the dynamo will be sacrificed, whilst at the same time the desired result will not be obtained, and it will be found that it is absolutely impossible to obtain a position of sparkless commutation for the brushes in any dynamo in which the field is weak.

If the brushes were given a negative lead or lag, and, as shown in Fig. 29, brought under the tips of the trailing horns, violent sparking would, as we have already seen, at once ensue, for the short-circuited coils would be under the influence of the field they were leaving, and not under that of the field they were entering, so that the induced short-circuited currents would be in the same direction as that of the *a* series of coils which would be opposed by the main *b* current, and we should have disastrous sparking and rapid wearing away of the commutator, which would be positive to the brush. Upon analysing the two bands of armature coils, we should find that the coils lying between the lines A B C D are now carrying the current in the opposite direction so as to induce a north armature pole, opposite the south pole of the field magnets, and a south armature pole opposite a north field pole, or, in other words, the induction would no longer be opposing the field flux, but aiding it, and would hence be a forward induction. It must be thoroughly understood that there is no peculiar virtue in commutating the current when the short-circuited coils are under the influence of field from the leading horn, except that with ordinary windings this is the only position where sparkless commutation can be secured, and that the condition for sparkless commutation is, as has already been stated, that the short-circuited coil when it passes from under the influence of the brush must carry a current similar in value and direction to that of the series of coils into which it is thrown.

In May, 1893, Mr. W. B. Sayers read a paper before the Institution of Electrical Engineers, in which he claimed that by means of a winding which he had patented sparkless commutation could be obtained with a lag of the brushes, and that thus advantage could be taken of the forward induction of the armature. It has been mentioned that, owing to the back induction, when a forward lead is given to the brushes the field flux is weakened proportionately to the output of the dynamo, and that to overcome this weakening of the forward induction, the series or compounding coils must be added to the field coils if a constant E.M.F. is required with uniform speed at all loads. Now if the armature back induction be converted into a forward induction, not only will no compounding coils be required, but also the magnetising force of the shunt coils need not be so great, as the armature will to a large extent create its own field. That this is so is not only evident from theory, but is borne out in practice by the fact that with a lag of the brushes a motor will run without any field coils, although the speed will probably be enormous, owing to the induced field being very weak and the value of ϕ small.

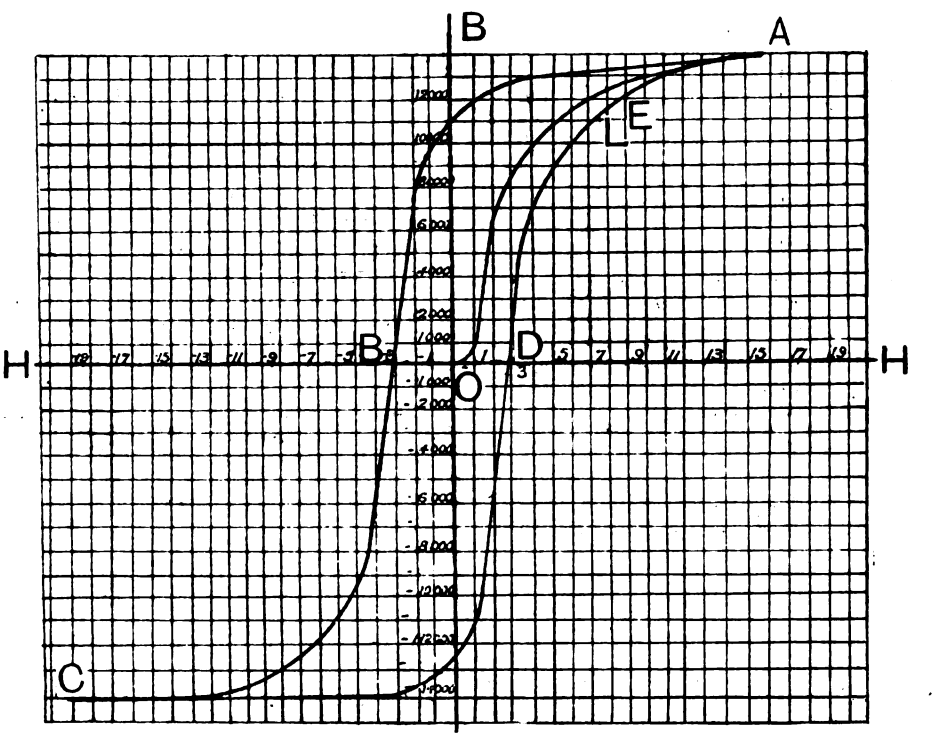

FIG. 28.

Fig. 30 gives a diagrammatic view of the arrangement of this winding, which is shown for a Gramme armature for the sake of clearness, although adaptable for either a Gramme or drum. There is first of all an ordinary closed two-circuit winding, and then interposed between each coil and its commutator section is a second coil, called by Mr. Sayers a commutator coil, wound behind the main coil. This coil is wound with the others, but in the diagram is shown below in order to avoid any complication of the coils. It is evident, as the short-circuited coils

Digitized by Google

have not yet reached the neutral plane, but are still under the influence of the trailing horns, that the coils to the right will be cutting a larger number of lines of force per unit time than those to the left, and hence will generate a higher E.M.F., and the resistances of the coils being the same, a larger current will flow round them. The object of this winding is to cause the short-circuited current produced in one set of coils to oppose the short-circuited current produced in the other to such an extent that the coil *d*, which is receding from the brush, may at the moment it passes from under the influence of the brush carry the normal current of the *b* series into which it is passing in the proper direction. In this, as in all other discussions on the theory of commutation, it must be remembered that if currents oppose each other along the same path, the resultant flow will only be the difference in their values.

Taking the output of the dynamo as 240 amperes, 120 will be due to the *a* series of coils, and 120 to the *b* series; and assuming that the two main coils, *d* and *e*, and the three commutator coils, *k*, *l*, *m*, generate short-circuited currents having the following values—viz., $d=60$, $e=120$, $k=120$, $l=240$, $m=420$—the currents which would tend to flow through the three lugs, *x*, *y*, and *z*, might be tabulated as follows:

In a forward direction to the commutator:

		y	*x*
Current due to *a*	60	40	20=120
,, *b*	20	40	60=120
,, *e*	—	80	40=120
,, *d*	—	—	60= 60
,, *k*	—	—	120=120
,, *l*	—	240	— —
,, *m*	420	—	— —
	500	400	300

In a backward direction from the commutator:

	z	*y*	*x*
Current due to *e*	80	—	40=120
,, *d*	20	40	— = 60
,, *k*	120	—	120=240
,, *l*	40	80	— =120
,, *m*	—	280	140=420
	280	400	300

Subtracting one from the other, it will be found that the currents through lugs *y* and *x* exactly balance each other, and that at the moment when *x* passes from under the brush no current is flowing through its lug, but that the whole of the current has been transferred to the heel of the brush—the condition necessary for sparkless commutation.

Reverting again to the question of the magnetic circuit, it is seen that unless by means of this winding, when a lag can be given to the brushes and the field of the active horns strengthened, sparkless commutation is impossible with a weak field; and it has also been shown that if the field is very strong, and the neck of the pole-piece is made of a small sectional area, an unsymmetrical field will be obtained, owing to the action of the cross-induction in distorting the field unequally. It is necessary, then, for the designer to choose a proper magnetic density for his magnetic circuit, and this will be found when the induction of the iron is equal to that which obtains when the curve of the sample piece has just passed the sharp bend marked E in Fig. 28. If the designer works at this point, he will find that the small changes in the magnetising force, which must occur in practice with the running of the machine, will make little difference in the E.M.F. induced.

At this point the permeability of the iron is still greatly in excess of that of air, and in order to obtain the best results the air-gaps must be kept as short as is possible, otherwise there will be a large expenditure of power in forcing the induction across these gaps. All joints in the magnetic circuit must be avoided as far as possible, and where these are inevitable they must be well fitted together. Dr. Silvanus P. Thompson states, in his "Dynamo-Electric Machinery," that if the induction of a solid bar with a magnetising force of $H=70$ be $B=17,100$, if the bar be cut in eight, B will only equal 15,200, whereas if the bar be compressed so as to close the joints and $H=70$, and B for the solid bar equal 17,200 for the bar cut in eight and compressed, B will equal 15,700. These figures show not only the bad effects of joints across the path of the magnetic flow, but also the difference which exists between a poor and a well bedded junction of two pieces.

We noticed that the curve of the complete cycle for the magnetisation and reversal of magnetisation of iron enclosed an area, and that this area represented the work done on the iron during the process of the operation. This work is completely lost for all useful purposes; we start with a piece of iron, magnetise it, reverse the direction of magnetisation, and then magnetise it again. We are then exactly as we started, and have effected no useful

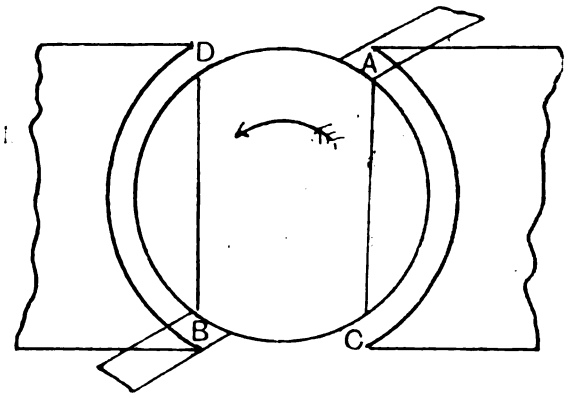

Fig. 29.

purpose, and yet have expended a certain amount of energy, and as energy cannot be destroyed, it will be found that it has been dissipated in a form we do not desire—viz., heat. It is evident that the size of the area, which is the measure of the work done, depends upon three things—the permeability of the iron, its retentiveness, and the strength to which it is magnetised.

What exactly occurs when a bar of iron is magnetised is not definitely known. Two theories have been advanced: that of Weber's is the one which is now almost universally adopted, and which is in accordance with all the known phenomena of magnetic induction. Weber proposes that

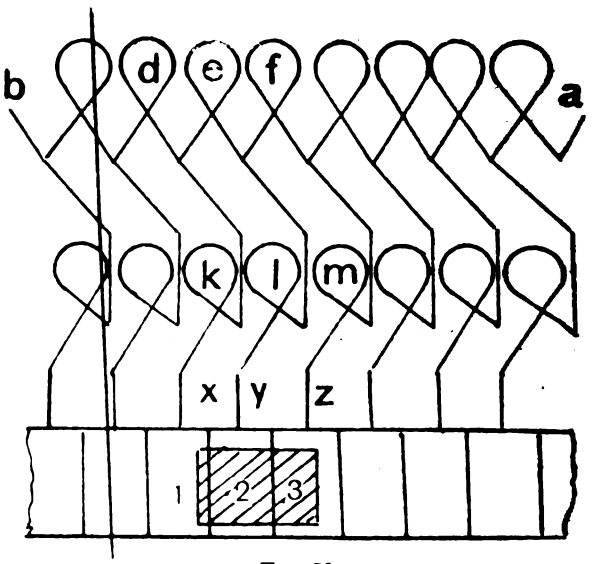

Fig. 30.

each molecule constitutes a small magnet, and that these magnets in an unmagnetised bar lie higgledy-piggledy, with their north and south poles pointing in any direction; or rather that they form closed magnetic circuits, so that there is no free magnetism. Upon the bar being magnetised these elementary magnets tend to set themselves in parallel lines, with all their north poles pointing in one direction and all their south poles in the other. It will be evident that if this is the case a very weak magnetising force will liberate a large number of these magnets from the closed circuits in which they are only loosely held, and cause them to take up the longitudinal direction. As the magnetising force is increased, more elementary magnets will be turned into the new direction, but as the number

Digitized by Google

to be turned is less, a smaller quantity will have their direction altered for an equal increment in the magnetising force. As the value of this force increases, fewer and fewer molecules will be diverted, until only those will be left which have become wedged into their primordial position, and if finally by the application of a very intense magnetising force these molecules are compelled to change into the required direction, no further increase will add to the strength of the induction in the iron, and the bar is said to be saturated. This it will be seen agrees fully with what does occur when a bar is magnetised, as shown by the curve in Fig. 28. Now, upon the magnetising force being removed, the molecules will take up their old positions, and again from closed magnetic circuits, and the bar will be demagnetised, or, rather, as a few molecules will become wedged in their new position the bar will still retain a little of its magnetism. This is what we find occurs in practice, and this magnetism is called, as we have seen, the residual magnetism. Again, if Weber's theory be correct, we should expect that it would be harder to magnetise a specimen in which the grain was close; the residual magnetism would be greater than in one where the grain was open, as not only more molecules would become wedged, but that also there would be more opposition to any of them moving. This also is found to be the case. A permanent magnet may be made of steel, but not of cast iron. Further, if during the process of magnetisation the bar be struck with a hammer the molecules will be moved, and will be freer to take up a new position, and so the effect of the magnetising force will be increased. This we find to be the case in practice, whilst the converse is also true, that a bar of iron at once loses much, if not all, its residual magnetism if sharply struck, which is what we should naturally expect if Weber's theory be true.

Accepting, then, this theory as correct, it is perfectly evident that if a piece of iron be not strongly magnetised—*i.e.*, if the molecules be not held in their position by means of a high magnetising force—small extraneous local magnetising forces will alter to a considerable extent the disposition of the molecules in their immediate neighbourhood, so that whilst we have seen that the hysteresis of an armature core varies as the induction, it is also evident that if the induction due to the field coils is not high, that due to the flow of current through the armature coils will greatly distort the resultant field, and also the self-induction of the short-circuited coils will be largely augmented, as the lines of force created by the stopping and starting of their currents will have a much easier path through the iron of the core than they would were the induction of the armature greater.

The designer is here met by a contradiction in his requirements. To minimise the loss due to hysteresis, the induction must be low, while to prevent trouble from the armature reactions the induction must be high, and one or the other must be sacrificed, or else a compromise must be made. Financial considerations must always have a great weight in determining any question of compromise, as for mere philosophical reasons it is not much good building a perfect machine if the cost is so great as to make the price prohibitive, and financial considerations are on the side of high induction and less weight of iron in the armature. The density of the lines of force is primarily governed by the heating, and loss of efficiency due to hysteresis and Foucault currents, both of which vary directly as the density and the number of revolutions per unit time; it also depends to a certain amount upon the special purpose for which the machine is required. If it is necessary to keep the magnetic flow constant with varying loads, the induction must be high in order to make the whole magnetic circuit insensitive to varitions in the magnetising force, for, as seen from Fig. 28, a large variation in H will make little or no difference to B if the induction be pushed far up the curve towards A. If, on the other hand, it is desirable that the E.M.F. should rise as the output in amperes is diminished—*e.g.*, a shunt-wound dynamo for charging cells—the induction should be much lower than in the former case. Consequently the induction permissible will vary between large limits according to the speed, and also that the purpose for which the dynamo is to be employed, and may be, according to Mr. A. E. Wiener, anything between 35,000 per square inch and 130,000 per square inch. In the introductory remarks it was stated that it was not sufficient when building a dynamo simply to copy the design of the first machine available, as the conditions under which the two machines had to work might be totally different, and then equal results would not be attained. The density of the lines of force in the armature core is a case in point, and should serve to show the student that each machine must be designed both from a knowledge of first principles and also in accordance with the modifications requisite for the special work it has to do.

The designer constantly finds, as in the case of the armature induction, that compromises have to be made and that the electrical or magnetic requirements are at variance with good mechanical practice (*e.g.*, the building up of the commutator), and throughout the whole design it is essential that he should not be slavishly bound to one side, as it were, and sacrifice all mechanical principles on the one hand, or all electrical or magnetic principles on the other; for the good designer is he who will keep the salient features of each and build a machine which, if not perfect, is in agreement with the fundamental principles of electrical and mechanical science.

PRACTICAL NOTES ON ELECTRIC MAINS.

BY A MAINS ENGINEER.

(*Continued from page 727.*)

2. *Cable Laying and Jointing.*

It will be best, perhaps, to commence this subject by reviewing the chief method of distribution, as regards class of conductor, material, and method of work, leaving jointing for the time to be treated later. The systems of distribution mostly in use are four in number, and can be classed as follows: drawn-in or conduit systems, solid laid systems, armoured cable systems, and bare copper systems.

Taking these systems in order as they stand, the conduit system, perhaps, appears better in theory than it works out in practice. For instance, we should like to use a conduit in our most busy streets, yet these are the very streets where we cannot find room for a conduit, as, above all, they are the streets which are most blocked by gas and water mains and their services, surface-water drains, cellar roofs, etc. It is very nice to think that in a particularly busy street, where it is almost impossible to open the ground on account of traffic, if we put in a conduit we shall, at the time of a fault occurring on a cable, be able to draw out the faulty cable and draw in a good one almost unknown to the general public using the footway. It seems hardly worth while to put in a conduit in a sparsely populated district, yet this is the district where we could best instal one.

If, however, conduits can be placed in our most busy streets, they will be found to answer very well in the case of an alternating supply, but not so very well in the case of a continuous-current supply, owing to electrolysis. It is quite unsafe to draw into a conduit lead-covered cables for use with continuous current, even if the conduit be made of earthenware; and if the cables are not lead-covered, there is great danger of the insulation and the protecting yarn or tape perishing before long owing to being continually wetted and dried as the weather changes. If it is intended to use a conduit for continuous-current work, cables insulated with vulcanised bitumen or rubber will probably give better results than others, as these materials have been found to stand fairly well in damp conduits, and they, moreover, are better suited to the strain of drawing in than cables covered with fibre or paper, this, of course, taking for granted that lead-covered cables will not be used. Whichever insulation is used, the insulating material must be well protected with braid, tape, or yarn, and in the writer's opinion ought to be so protected to at least twice the thickness usually employed; indeed, this protecting covering might well be made much heavier than it usually is on all cables that are not lead covered and for whatever system used, not speaking, of course, of house installations.

In cases where electrolysis has put in an appearance, it has

Digitized by Google

been found that the lead covering of the cable has been nearly of the same potential as earth—that is to say, a water or gas main—and that the potential of the surrounding ground has been anything up to five volts above that of earth, thus causing the destruction of all the metals at the lower or earth potential. This great difference of potential between the lead covering of a cable and the surrounding ground would obtain more often where the cable was lying in an iron pipe, and where the surrounding ground was of a sandy nature; so that it follows that no attempt to earth the lead of any continuous-current cables should be made, but an attempt rather to insulate them from earth.

Concentric or triple-concentric cables for use on an alternating supply can be made with a dielectric of any material liked, as they can be lead-covered with impunity; such lead covering is, however, better left without a serving of braid or yarn The insulating material for such cables will be found to answer well if made of fibre or paper, and, in the writer's experience, have answered better than rubber or bitumen when used in conduits.

Although perhaps not bearing directly on the question of conduits, it may be as well to state here that in a continuous-current supply the negative cable is the one that gives the most trouble, a positive earth being comparatively rare, so that if in the case of a three-wire network triple-concentric cables are used, the inner core should be made the negative pole, the intermediate being the positive and the outer the neutral and earthed conductor. The use of concentric cables would, of course, enable the size of the conduit to be materially decreased—that is to say, so great a number of pipes or ducts would not be required. If single-conductor cables are used, a rule which must never be broken is that no more than one cable must be in one pipe, however large the pipe. Even if two or more cables of comparatively small sectional area are used to make up the size necessary for one pole, yet each of these should be in a separate pipe, as if one goes wrong it could not be withdrawn without damage to its fellows if all the cables so used were in one pipe, owing to the fact that the cables when so drawn in would twist together. These remarks about single-conductor cables apply only to continuous-current supplies.

Some engineers lay down conduit systems in which they use the conduit for their feeder cables, laying down the distributors on some other method outside the conduit. This appears to be a wrong idea, because taking it for granted that we have laid our conduit in a busy street, and that as a rule it is the distributor that goes wrong and not the feeder, it is therefore the distributor that we shall most likely have to withdraw; and this can be so easily done with a distributor, even after it has been tapped in many places with service joints, as it can be cut up and pulled out in short lengths, a short length of new cable being pulled in to replace it. In this way very few consumers would have to be changed over in one day, as the composite, bad and good cable, would be charged at one end only, and that the good end, until it was good right through. The bad end could be supplied through a fuse inserted between the good and bad parts. All the succeeding good pieces can be easily joined together in a service box; this method of joining will be mentioned when speaking of jointing generally. When arranging for a conduit, care must be taken that enough ducts are allowed for, so that the ground has not to be opened again.

It will now be necessary to turn our attention to materials used and methods of using them. Conduits are constructed of glazed earthenware, sometimes in the form of single-collared pipes, and sometimes in short lengths, each length containing any number of ducts; of cast-iron socketed pipes; of zinc pipes; and sometimes of bitumenised paper tubes The single-collared earthenware pipes, the short lengths of multiple ducts, and the cast-iron pipes can be laid direct in the ground, the joints of the single iron and earthenware pipes being made after the pipes have been placed in position by neat cement being forced into the sockets in each case. The zinc and paper tubes are laid on a concrete bed and covered up with concrete. So that as the multiple duct earthenware conduit is made of very hard material, and can be laid direct in the ground, except for the necessary concrete round the joints, it will probably give the best result as to minimum amount of room required. If this class of conduit is used, or, for that matter, whatever class is used for distributors, care must be taken that sufficient room is left between one cable and the next cable or duct to allow the service joint-box to be fixed or a straight joint to be made. As it is almost impossible to make a good job when putting on a service to a cable in a conduit unless small brickwork boxes are provided, these will have to be built—the conduit being cut away as required—but can be built when and where circumstances require them. They need have no bottoms, and, indeed, are better without them, as any water which gets in from above immediately soaks away. If the conduit is laid low enough in the ground, the brick box can be covered with an ordinary rough flag, ground being filled in on the top to the necessary level for the paving flag. A glance at the accompanying sketch (Fig. 1) will show at once the arrangement meant. In

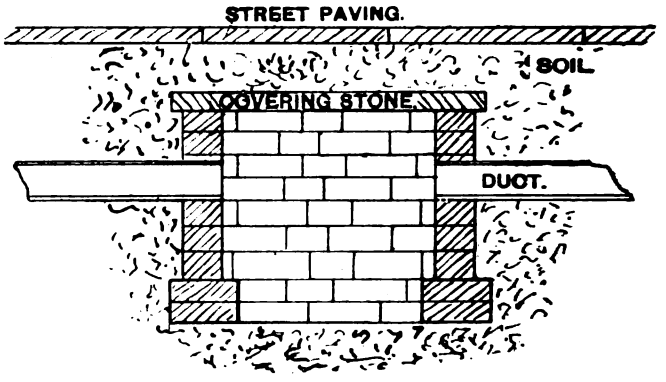

FIG. 1.—Brick Service Box.

some cases these brick boxes are built when the conduit is laid, and a box is usually placed opposite to every other party wall, thus making allowance for two services—one to each adjacent building If built at this time the boxes are usually brought up to the paving level and provided with a cast-iron frame and cover, the cover being filled in with a fine concrete made of granite chippings and cement, in the proportion of 3 of the former to 1 of the latter. Iron frames so placed must be earthed, preferably to the nearest water-main. The zinc and paper tube conduits have nothing to specially recommend them, the paper tube least of all, as if once a cable is drawn into such a tube and left there a few months, it needs a traction engine to draw it out again, because the cable sticks to the bitumen used with the paper; in fact, it is possible to pull a small cable in two and then not start it. The ducts in any conduit are best cylindrical in form.

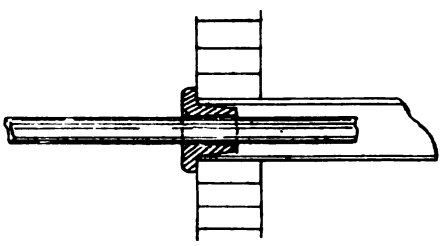

FIG. 2.—Plug for Duct.

The conduit, if constructed of earthenware, will need some protection on top, such a protection as will stand the blow of a pick, and also one that will warn the user of the pick that he must use care. A layer of concrete has been tried, but when the average navvy comes to a bit of concrete in making an opening he generally lets go all the harder until he has smashed through it. Iron, again, if cast, would fly in pieces when struck, and if wrought would soon rust away; moreover, both would be very expensive. In actual practice a board of pine or elm about 1¼in. thick, creosoted or boiled in Stockholm tar, has been found to give the best results, as when struck with a pick the pick usually sticks in, giving the user not a little trouble to get it out again, thus giving him plenty of warning that there is something unusual in the ground. If the conduit were constructed of thick cast-iron pipe this covering would not be needed, but cast iron cannot be recommended for conduits, as there seems always to be a more or less deleterious action going on between the cast iron

Digitized by Google

and the cable, whichever supply is used and whatever the class of cable employed.

Whichever class of cable or conduit is used, the ends of the ducts containing cables should be stopped with a solid rubber or wooden stopper. The stopper would necessarily be made in halves, the outside of the stopper tightly fitting the duct, a circular boring through the centre clasping the cable, as shown in Fig. 2. The use of such stoppers prevents corrosion of the cables, so often found at the ends of conduit ducts, probably caused by the deleterious action of the glaze on the stoneware; they also prevent the accumulation of gas in the ducts, and to this end any empty ducts should also be stopped.

When laying a conduit, a galvanised iron wire, say of No 10 B.W.G, should be threaded through each length as laid and left in; this wire can afterwards be used to draw in the drawing-in rope, and will save a lot of work in the end When drawing in cables, if the run of the conduit be fairly straight, a length of 200 yards is not too much to pull in at once, as it is always well not to flake the cable more than necessary. Of course, the heavier the cable, the more men will be required for drawing-in, and a man should be stationed at each intermediate box to direct the cable as it runs past him, and to keep it from rubbing by the application of some lubricant. A good lubricant can be made of pure tallow worked up with powdered blacklead. This should also be freely applied to the cable at the paying-in end.

The drawing-in rope must be securely fastened to the copper of the cable, and in the case of a concentric cable each conductor should be attached to the rope This fastening can best be made by providing an iron eye or

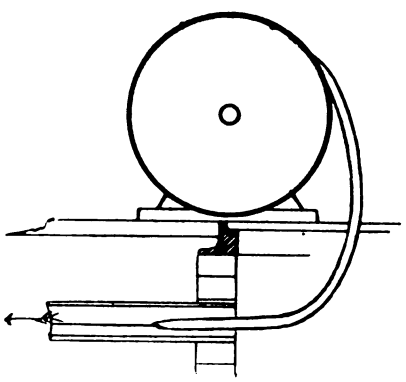

FIG. 3.—Drawing in.

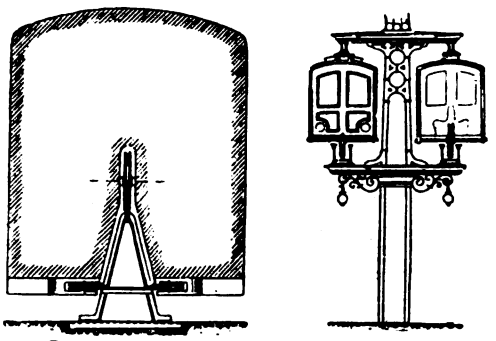
thimble which should be wire spliced on to the end of the rope, a neat taper being made by the splice, which can then be whipped over with hard twine. The cable conductor or conductors are then halved, and each half passed through the eye in opposite directions and then bent backwards to the cable, being laid neatly down, and three or four copper binders fastened over and round all the strands. The whole cable end is then to be taped up and painted with waterproof compound to prevent any water which may be in the duct from getting into the cable. It will be found that 20 men will be sufficient for the whole work of drawing in, say, a 200-yard length of $^{37}/_{16}$ concentric lead-covered cable. This will allow four men to be stationed at the drum. The drum is best mounted about three yards away from the drawing-in box, and so mounted that the cable comes off underneath the drum, as this way there is less risk of damage to the cable, because the cable is more in line with the duct than it would be if it came off the top of the drum A very good way of mounting the drum is shown in the sketch (Fig. 3); in this case the cable does come off the top of the drum, but is still as much in line with the duct as it can be. As the cable is running in, it must be kept off the edge of the box on the paying-in side. The foreman in charge of the work should stand near the drum during the whole operation, except occasionally to look at the intermediate boxes to satisfy himself that the cable is running without undue rubbing. He should be provided with a shrill whistle. Before pulling in a cable a swab of spun yarn or waste should be attached to the wire which has been left in the duct, and pulled through in advance of the drawing-in rope; this will clear the duct of any dirty water which may be there.

(To be continued.)

THE BARMEN-VOHWINKEL SUSPENDED RAILWAY.

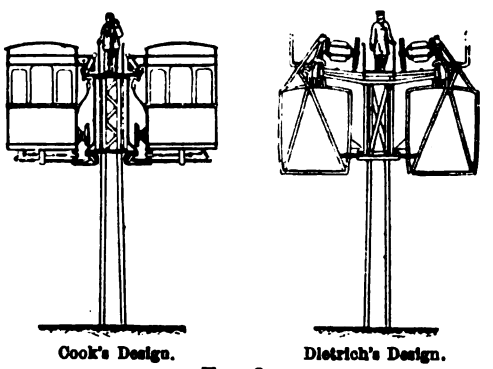
In the *Centralblatt der Bauverwaltung* there was commenced on Oct. 13 last a series of articles describing in detail the new suspended railway between Barmen and Vohwinkel. It will be remembered that a section of this railway was recently opened by the German Emperor. We venture to quote the following details of the railway from the above-mentioned source of information, to which we are also indebted for the drawings here reproduced.



Lartigue's Design. Beyer's Design.

FIG. 1.

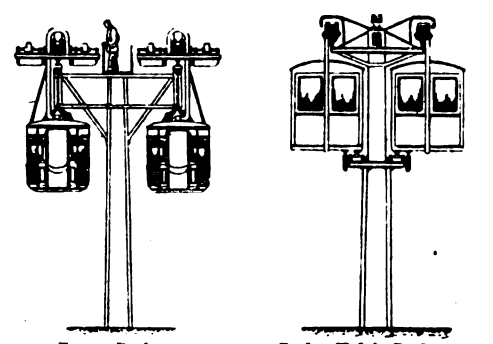
The Barmen-Vohwinkel Railway claims to be the first railway constructed for local passenger traffic in which the trains are supported directly under the track. That the idea of passenger conveyance by means of



Cook's Design. Dietrich's Design.

FIG. 2.

hanging or suspended cars, instead of by ordinary adhesion railways, contains much that is fascinating, is proved by the numerous proposals which have been made to construct such railways. These proposals must be looked upon as forerunners of the Barmen-Vohwinkel Railway, but their pros-



Enos's Design. Perley-Hale's Design.

FIG. 3.

pects of success were injured by the fact that in their design it was sought to embody the principle that all lateral movement of the cars should be as religiously avoided as in the case of ordinary surface railways. It is abundantly evident that to insist upon this condition would be to preclude the possibility of a mono-rail track. This circumstance has had a considerable influence upon the construction of such railways. The centrifugal force exerted round curves necessitated provisions of a similar nature to those for surface railways; to the perfecting of the rail track especial care had to be devoted; the points were complicated, and so on. Some inventors placed the centre of

Digitized by Google

gravity of the car above the rail, others on the same level, and yet others below the rail. The first method of construction is represented by the designs of Robinson and Palmer (1826), Fell, Haddam, Le Roy, Stone, Lartigue (Fig. 1), Decauville, Meigs, and Behr, who provided that the cars should straddle the bearing rail, as in Lartigue's design (Fig. 1). Below the bearing rail are provided guide rails, as shown, to take the thrust due to the lateral force acting upon the car. As regards the number of these guide rails, Behr has gone to the farthest extreme. Besides the bearing rail he provides four guide rails. A single car, which was employed upon an experimental railway of the Behr type at Brussels, possessed no less than 40 bearing wheels. The design by Beyer (Fig. 1) embodies an equivalent arrangement, the auxiliary rails being in this case supported by special girders fixed above the cars. To the second group of the suspended car types, in which the bearing rail is arranged to the side of the car's centre of gravity, belong the types designed by Cook (Fig. 2) and Dietrich (Fig. 2). The first-named inventor exhibited a small model at the Chicago Exhibition in 1893. Dietrich's design was evolved in 1895. To the third group belong, among many others, the types of construction proposed by Enos (Fig. 3) and Perlay-Hale (Fig. 3). Enos employed two slanting stay wheels arranged above the car body as shown, while Perlay provided guide wheels underneath the car. The structural and working disadvantages involved by thus staying the body of the suspended car are entirely absent in the Langen type of car. In this latter type all means of auxiliary support have been discarded, the car being left free to move laterally. By making this radical departure from previously conceived types of suspended railways, Herr Langen and his partner, Herr Feldmann (Government architect) have succeeded in endowing the new form of railway with a high standard of excellence. The railway having no precedent of its particular kind, the design, of course, embodies many originalities. Problems hitherto unknown to railway work had to be considered and practically solved—in what manner we shall see. Not only was there no existing example of a viaduct of suspended track required which could serve as a precedent, but details of the cars, of the railway itself, the points, cross-overs, and other arrangements, had also to be severally considered, and designs evolved to suit the unique conditions imposed.

Unfortunately, the inventor of the railway—Privy Councillor Eugen Langen—did not live to witness the completion of his pet scheme, nor, indeed, the commencement of its practical realisation. Death claimed him when he was in the midst of preliminary preparations for executing his novel scheme. At the beginning of 1893 he had entrusted Herr Feldmann with the elaboration of the proposed scheme. In the same year patents were applied for, and practical experiments on a limited scale made; also the preliminary plans for the Barmen-Vohwinkle suspended railway submitted.

The experimental railway—an O-shaped loop, consisting of two semi-circular end sections of 33ft. radius, connecting two straight rail sections 66ft. long, which formed the sides of the loop—had two bearing rails. The track had a gauge of 18in., while the experimental car was mounted upon two four-wheel bogies, which allowed it ample side play. Langen at first adhered strictly to the two-rail type of track, and was supported in this by expert advice. The success obtained with the experimental track also seemed to bear out his theory, and the original plans submitted for the Barmen-Elberfeld line therefore provided for a two-rail track. The scheme, however, was destined to meet with considerable opposition before its practical realisation in a modified form. Most of this opposition had its origin in that in the townships concerned the construction of electric tramways of the ordinary type by a local company was under consideration at the time. Also the opposition of the general public to a municipal undertaking of the description proposed made itself felt. However, the scheme was actively promoted, and eventually won on its merits. The greater security to life offered and the possibility of a higher speed being obtained, were points which told greatly in its favour. By an agreement entered into at the end of 1894 by the united municipalities of Barmen and Elberfeld, the requisite powers to construct the railway were conferred upon Messrs. Schuckert and Co., of Nürnberg. It was subsequently decided to continue the railway to Vohwinkel, but further delay occurred in making the final arrangements. Meanwhile,

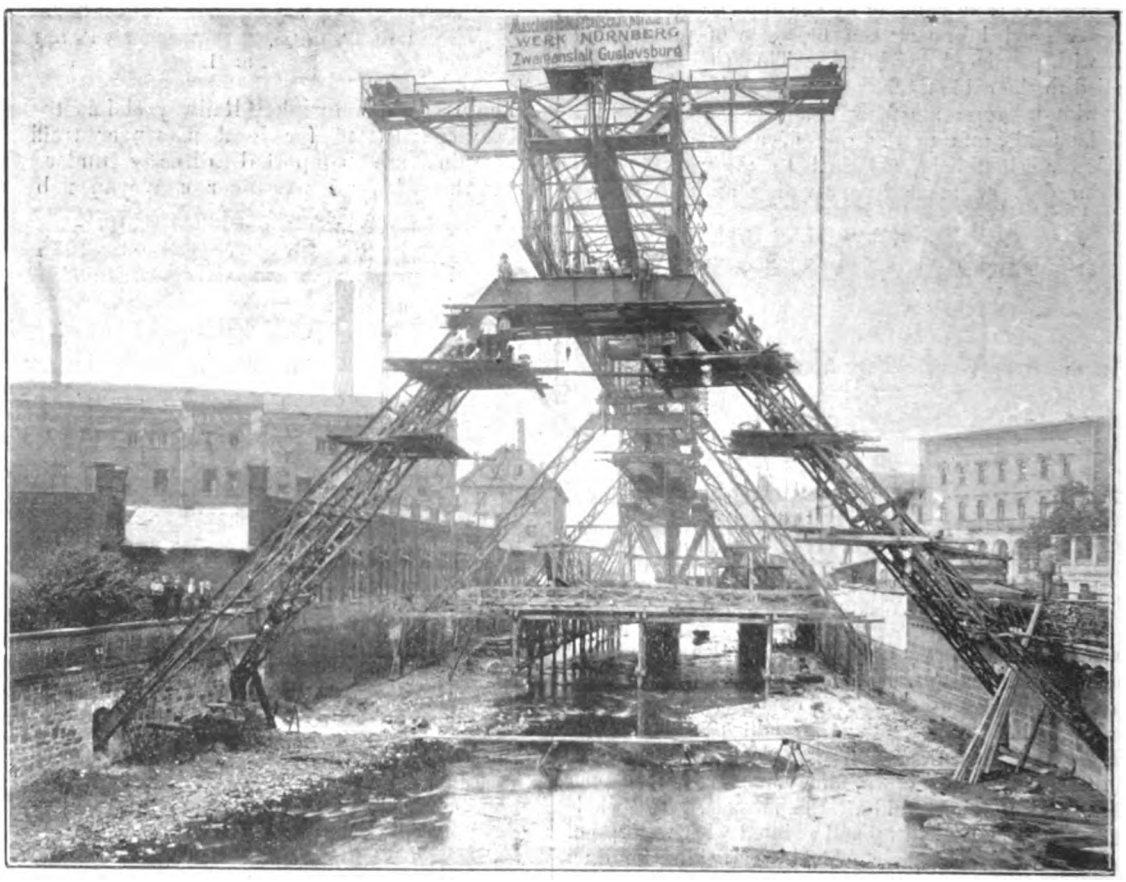


Fig. 4.—Wupper Section in course of Erection—Barmen-Vohwinkel Railway.

Digitized by Google

however, an experimental section of track constructed on the mono-rail principle was erected. So successful were the results obtained that even the town authorities urged the adoption of a mono-rail track, which course was eventually decided upon. The actual construction of the railway was commenced in 1898, and at the beginning of the following year a trial run was made over the first completed section of the line. A length of 2¾ miles is already open for traffic, and another 2¼ miles is expected to be ready shortly, though the Barmen section, which will be 3¾ miles long, is not likely to be completed before 1902.

For a distance of nearly 6½ miles the railway is suspended over the River Wupper, and follows the main road for another 1¾ miles to the railway station at Vohwinkel, where it joins a network of electric tramways communicating with Ohligs, Düsseldorf, Solingen, and Mettmann-Wülfrath. For the most part the course of the railway is of a winding nature, the sharpest curves being of 300ft. radius, except on the sidings, where curves of 26ft. radius are the rule. The line reaches its lowest level at Sonnborn, which lies about 105ft. lower than Ritterhausen, where the Wupper section commences. From Ritterhausen to Sonnborn, a distance of 6½ miles, the line, therefore, makes a gentle descent. But numerous rises and depressions occur *en route*. These, however, are so arranged that the trains proceed over the track at an uniform speed. From Sonnborn onward to Vohwinkel the track rises again about 130ft. On the whole the gradients are moderate, though at the Vohwinkel end of the line gradients up to 1 : 22 occur. There are 20 stations arranged at intervals of from 350 to 1,100 yards along the route, which gives a mean distance between stations of 760 yards. The superstructure of the railway is of a substantial character (as will be seen on referring to Figs. 4, 5, and 6), which show it in various stages of completion. The vertical girder supports are spaced at intervals of from 70ft. to 100ft., and straddle the

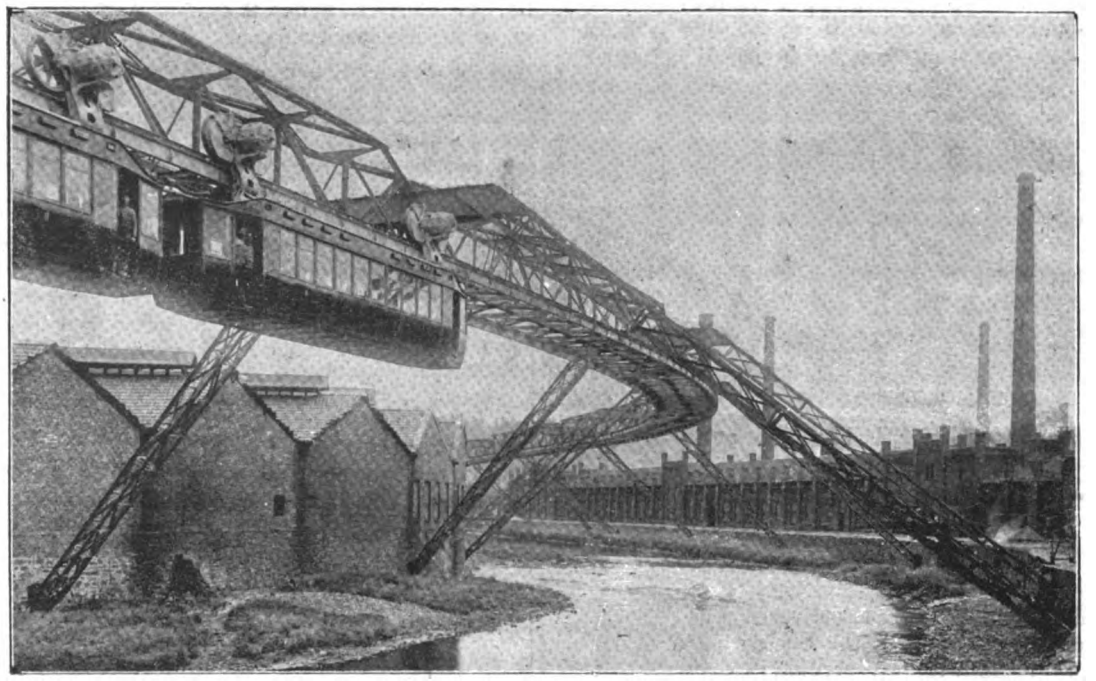

FIG. 5.—Wupper Section—Barmen-Vohwinkel Railway.

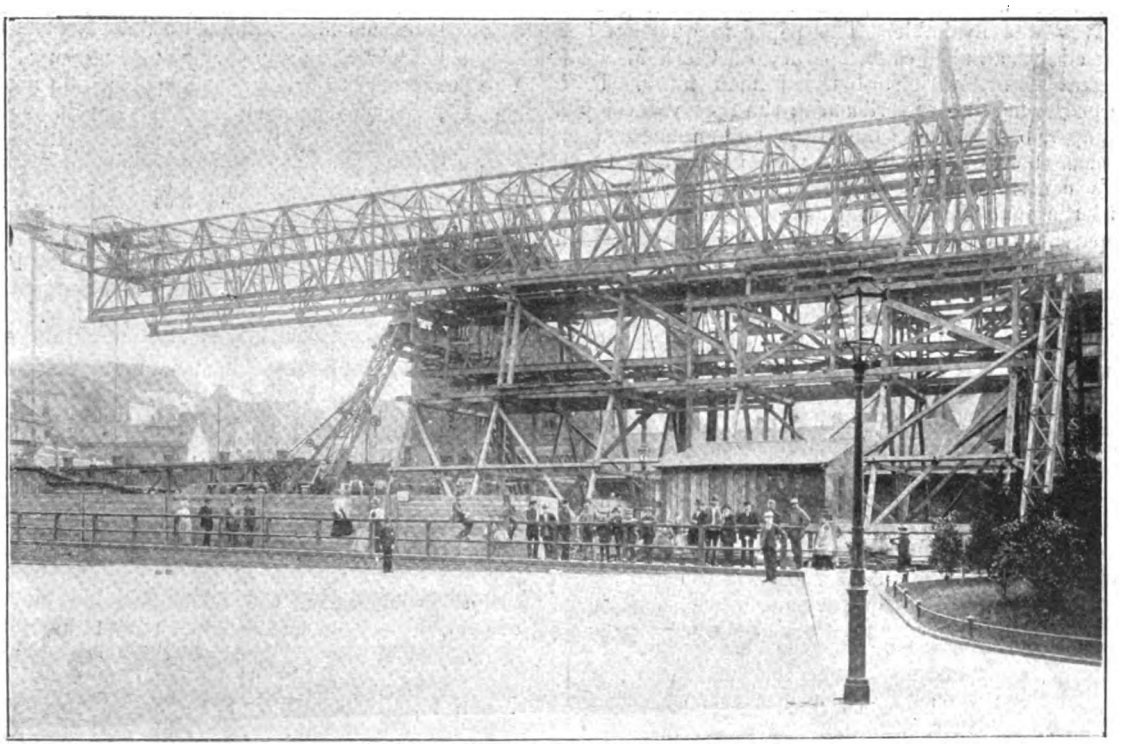

FIG. 6.—Superstructure in course of Erection—Barmen-Vohwinkel Railway.

Digitized by Google

river (as shown in Fig. 5), while square frames (Fig. 7) are employed over the roadway section of the line. At intervals of from 150ft. to 1,000ft. fixed groups of supporting yokes are placed, with an expansion joint half-way between them. The intermediate vertical supports are provided with ball and socket joints, and can therefore yield to temperature effects in either direction, whilst the fixed supports take up the longitudinal thrust of the superstructure due to the expansion. Since the supporting yokes of the several forms mentioned are subjected almost exclusively to direct pressure, and only in a very moderate

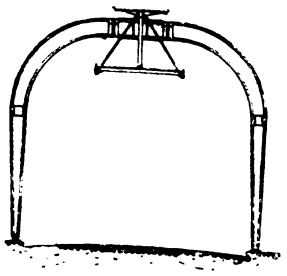

FIG. 7.—Portal Frame.

degree to a bending action, it has been possible to adopt the light braced girder type of construction shown.

ELECTRIC OSCILLATIONS.

The third Cantor lecture delivered by Prof. J. A. Fleming on Monday last at the Society of Arts did not deal quite so much with the oscillatory currents as those which preceded it. The lecture was devoted rather to the means of propagation of the electric waves through space. The lecturer explained that it was now generally accepted that all theories of action at a distance must be given up, and that phenomena connected with the action of distant bodies on each other required the presence of a transmitting medium. It was not until 1864, when Clerk Maxwell read his most interesting paper on the dynamic theory of the electromagnetic field, that any reliable explanation of what takes place in transmitting electrical waves was available. The paper in question had been classed by an able contemporary of Clerk Maxwell as the greatest production of the human mind. Prof. Fleming proceeded to give a *résumé* of the theory developed in this paper, but at the same time he reminded those present that there was much more than he gave in Clerk Maxwell's contribution to science. There were certain things in the investigation of this great scientist which were apparent, and there were other conclusions which could be deduced which were not at all clear. In fact, there were certain things in the investigation of this great scientist which were not at all clear, but which might be more understood as time went on. The author himself had said that his book was written with the idea of educating himself (Clerk Maxwell) and not for the public. But he intended afterwards to write two more volumes to explain the first. Unfortunately, however, his life was not spared to enable him to do so. Prof. Fleming went on to explain that there were two complete systems treated of in the paper by Maxwell—*i.e.*, the electric and magnetic systems. The various similarities of these two systems were gone through, as were also their circuit laws It was then shown that any displacement in space, caused, say, by an electric discharge, was propagated in waves, and that in these waves there were both electric and magnetic phenomena closely interlinked. An interesting diagram was then shown to illustrate that a displacement of an electric charge produces a magnetic force which tends to cause equal and opposite electrical displacements in the surrounding media. In this way the waves were propagated outwards much in the same way as the circular waves caused in a pond when a stone is thrown in. The next point to be determined by Maxwell was the velocity of the displacement. The lines on which the investigation proceeded were too long to give in a one-hour lecture, but the investigation could be simplified on the assumption that of the total energy of the wave half was potential energy and half kinetic energy. On this assumption, if E equals the maximum electric force, H equals the maximum magnetic force, K equals the dielectric constant, and μ equals the magnetic permeability, the following equation would be obtained:

$$\tfrac{1}{2} K \left(\frac{E^2}{2}\right) = \tfrac{1}{2} \mu \left(\frac{H^2}{2}\right).$$

But under the well-known laws of the electromagnetic circuit, $E = v\ B = v\ \mu\ H$. From the above equations $v = \frac{1}{\sqrt{K\mu}}$. The v in the equations represent the velocity of displacement which, when multiplied into the total flux, B, gives the E.M.F. in a unit length of the wave. The next point for consideration was that whereas K and μ for air are always assumed as unity, we had not a knowledge of their absolute value. In 1856, however, a method had been found to ascertain the product of K and μ, although neither of the quantities was known absolutely. The lecturer referred to the fact that v was the ratio between the absolute units of the electrostatic and the electromagnetic system. It was then found experimentally by Profs. Weber and Kolrausch that this velocity was practically the same as that of light, being equal to about $2{\cdot}99 \times 10^8$. Another step in the investigation was reached from the refraction of light as a ray enters a denser medium from the air. It was proved that the sine of the angle of incidence and refraction were proportional to the velocity of light in the media respectively. This velocity was proportional to the product of K and μ, and as μ was practically the same for the great majority of substances, this afforded a means of ascertaining the dielectric constants, as they should be equal to the square of the refractive index of the various substances. In Clerk Maxwell's time these properties had not been determined for a great many substances, and hence he was only able to apply this reasoning to a limited number, many of which gave discordant results. As an example of substances which agree with the above law, the following may be instanced:

	Dielectric constant.	(Refractive index)².
Sulphur	4·72	4·89
Paraffin	2·3	2
Petroleum	1·9	1·92
Petroleum oil	2·07	2·07

As an example of those substances which do not agree with this law, a very numerous list can be given, such as:

	Dielectric constant.	(Refractive index)².
Glass	6·57	2·37
Calcite	7 7	2·7
Mica	6·64	2·54

The next portion of the lecture was devoted to the description of a number of experiments made by Prof. Dewar and the lecturer on the dielectric constant of various substances which do not agree with the law. They found that the dielectric constant was largely influenced by temperature, and hence undertook an investigation of the properties of the various substances at exceedingly low temperatures, such as could be obtained with liquid air. In practically every case it was shown that as the temperature of the substance approached zero, the dielectric constant became very nearly equal to the square of the refractive index. Experiments were given with the apparatus used in these determinations. Particular interest centered round the use of liquid oxygen, because in this case μ was not unity. Careful experiments had shown that μ for liquid oxygen was equal to 1·0041, while K had been determined by the lecturer and Prof. Dewar to be 1·491. Another experimenter, Hasenochal, had also determined K and found the value of 1·465. If the mean of these two results were taken, one then got that K μ was for oxygen 1·484, whereas the square of the refractive index was 1 4837. As showing the influence of temperature on the dielectric constant the following figures were given:

	Dielectric constant. 15 deg. C.	Dielectric constant. -185 deg. C.	Refractive index².
Water	80	2 4	1 78
Castor oil	4 78	2·14	2·5
Glycerine	5·6	3·2	—
Olive oil	3·16	2·18	2·13

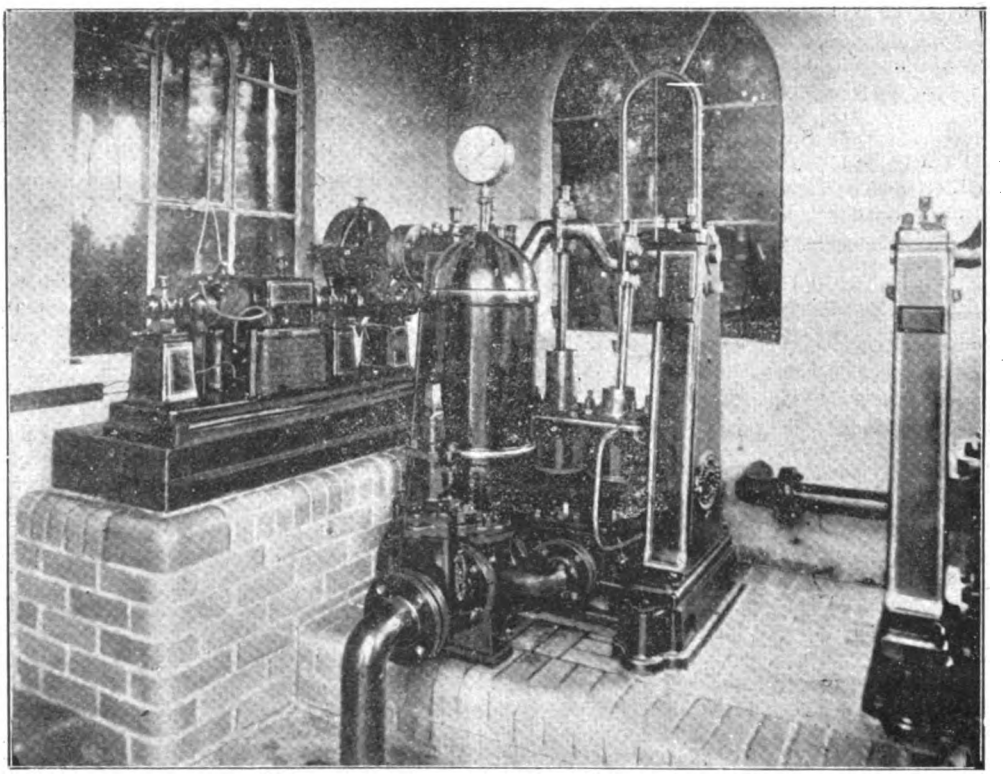
Digitized by Google

Attention was drawn to the fact that the similarity between the dielectric constant and the refractive index^2 occurred in substances whose composition was rather complex. The empirical law devised by Thwing was given for predetermining the value of K for these complex substances, and the lecturer stated that it gave fairly accurate results. In the course of the experiments it was also found that the frequency at which the condensers used in determining K were charged and discharged had an effect on this constant. Increase of frequency, like the lowering of temperature, tended to bring K more nearly equal to i^2. This led the lecturer on to a *résumé* of the various ether theories which have been in vogue during the century. These could be classed under three heads. By the first it was assumed that ether was a rare gas, but this had to be abandoned, as had also the theory that it was an elementary solid. The theories developed by Dr. Lamor, known as the rotating ether theory, was at present most favourable. He commended Dr. Lamor on the subject to those present in order that they might learn that scientist's view on the great ether question and on electrons, which he considered to be strains in the ether. One deduction from the theory was that electricity was atomic in character, and that matter generally was a solid form of electricity. There was much to be gained by the study of these various theories, even if they should be discarded in favour of others in the course of a few years. Theories helped us to search for new facts which would not be discovered but for theoretical predictions. At the same time they helped us to rearrange the facts already ascertained, and in this way forwarded general knowledge.

ELECTRICAL PUMPING OF SEWAGE.

The tiny village of Combs, Suffolk, would hardly suggest to the casual observer the existence of an up-to-date sewage scheme. Recently, however, in conjunction with the adjacent town of Stowmarket, a sewage scheme has been introduced, and a number of gentlemen were recently invited to inspect the pumps erected in the above village.

The machinery consists of two sets, each set comprising a three-throw pump driven by an electric motor through worm gearing. The bearings of the motor are lubricated automatically, the worm and wheel run in an oil bath, so that no attention would be required other than to start the motors and stop them when necessary; but even this labour has been dispensed with by the use of automatic switches controlled by the level of the sewage in the sump adjoining the pumping station. These switches can be easily altered so as to make either pump start in advance of the other, and a convenient arrangement is to allow one pump to deal with the ordinary flow of sewage, the second pump only starting if the sewage continues to rise when one pump is at work; and as it is easy to make either pump take the lead, they can be worked alternately week by week or month by month as desired, so that both sets of machinery are kept in good working order and do an equal amount of work. The power is derived from the electric light supply of Stowmarket, distant about three-quarters of a mile, and as it was desired that there should be no great fluctuation of current likely to affect the electric lights burning on this circuit, an ingenious arrangement of dashpot, with multiple-contact automatic switch, has been used, which gradually switches on the starting current over a period of from five to ten seconds.



Electrical Pumping Plant at Coombs, Suffolk.

The engineers who are responsible for this very pretty and useful installation are Messrs. Taylor, Sons, and Santo Crimp, while the contract has been carried out to their entire satisfaction by Mr. Napier Prentice, of the Anglian Engineering Company, Limited, of Stowmarket. The accompanying illustration is reproduced from a photograph taken of one of the pumping sets. It was difficult to get a good position for taking this picture, as, owing to the very small space required for this class of machinery, the building containing the two sets of pumps is under 15ft. square. The absence of steam, gas, or oil engines enables the pumping station to be kept scrupulously clean. The interior of the building presents a very pleasing appearance, the foundations for the machinery being faced with choice coloured glazed bricks set on a tiled floor, while the highly-finished machinery itself is painted black and carefully lined with gold.

CARDIFF.—Work in the direction of laying the new track for the electric tramway system which the Cardiff Corporation have decided to provide is to be commenced on Monday next.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street London, E C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

ELECTRIC RAILWAYS.

The discussion on Mr. Langdon's paper at the Institution and its branches will, if it does nothing else, focus the opinions that are held upon the subject by competent men. It ought to do more—to plainly indicate the conditions under which electric traction on railways is commercially practical; by this we mean will be a paying introduction. Railways are of many kinds, because the necessities of modern civilisation are manifold. It may hence be preferable to restrict our remarks to one point, and to one point only, of this great problem. Those who have made themselves acquainted with the history of railways will know that the first railway in the modern acceptation of the term was that between Manchester and Liverpool, opened some seventy years ago, constructed under the genius of Stephenson. Here were two populous centres desirous of quicker means of intercommunication. Over two hundred years ago—in 1677—Sir W. Petty wrote these pregnant words: "There is much more to be gained by manufacture than husbandry, and by merchandise than manufacture." If any century has proved the truth of these words, it is the century just coming to an end. The necessities of manufacture and of merchandise have led to huge congeries of population upon suitable areas. The problem to be solved, or rather the one point to which we have alluded, is how to obtain free untrammelled means of communication between the various points in these congeries of population. Take Greater London as the worst case. We have ordinary street traffic, tramway traffic, underground and ordinary railways, yet the cry is, More facilities. Take any outlying populous district, such as West Ham or Greenwich and neighbourhood, with even the existing facilities an exasperating lapse of time is lost in getting to and from the City. If the attempt is made to go by train, the train has to stop at every station, and thus loses time to those whose destination is the terminal point. Under existing railway conditions it is almost impossible to decrease the time spent upon these journeys, and thus the question is raised, Is it commercially practicable—that is, payable—to directly connect two such centres by means of electrical traction or otherwise in order to avoid existing delays? We have more than once in recent years pointed out the seeming apathy of the great railway companies to the needs of suburban districts. They have hitherto seemed quite satisfied with developing to the greatest extent their lines as they exist, ignoring the increasing competition of trams and 'buses. Now, the railways have their freeholds. They can burrow under the existing lines in tunnels, or build above them on viaducts; they can adapt their stations to the delivery of passengers at the level of the ground, or above or below as they choose, with the one proviso insisted upon by the shareholders, that they make the change pay. They can adapt existing lines to a mixed traction system if that will help them, and this paper of Mr. Langdon's shows that the railway officials are not so unobservant as they were supposed to be. His figures may be incorrect, his

Digitized by Google

conclusions thereby imperfect, but that is merely a detail in the consideration of so vast a subject. It is not the first figures nor the first conclusions, but these modified after consideration by competent critics that concern us—the question is where, when, and how can electric traction be introduced so as to increase facilities for intercommunication. We might have pointed to the fact that a railway on the Behr system is suggested between the two populous centres, Liverpool and Manchester. Surely whatever arguments can be urged for its adoption, these are valid when considering the needs of Greater London. These needs are not met by the many projected deep-level lines as arranged at present, and which would do very little towards solving the problem before us. What is wanted is a number of express routes to distributing centres in the distant suburbs, and for such lines there is an ever-increasing prospect in the future.

REVIEWS.

The Technical, Industrial, Commercial Vocabulary, in English, French, and German. By M. HOSPITALIER. Published by *L'Industrie Electrique*, 9, Rue de Fleurus, Paris.

The author, in the volume now before us, has attempted something new in the arrangement of a technical dictionary, and one that enables a great economy to be effected in the space required. The principle followed by Mr. Hospitalier is to arrange in alphabetical order the technical words of all the three languages. These words are printed in Egyptian characters, and are, of course, in French, English, and German, mixed up indiscriminately. After each word, then, follows its equivalent in the other two languages. In order to distinguish between these, three distinct types are used. Thus, all the French equivalents to the words standing first in the line are printed in small capitals, the English words in italics, and the German words are in Roman characters. It hence follows that as soon as one is used to the distinctions, there can be no hesitation in using this vocabulary, because one has not first to search for the right section of the book, as is the case with most technical dictionaries, which to give the same results would be divided into six sections. In order to still further decrease the size of the book, the characteristic endings of a word only are given when the root is the same in each language; for instance, one line reads:

Collect- (EUR. *or.* or).

which means that the French word "collecteur" is equivalent to the English "collector," and also to the German word "collector." When a word has more than one general meaning, the translation of each of the meanings are given, but they are divided by the parallel sign (||) to indicate the different meanings. The author concludes his introduction by stating that the task of collecting these words has been no mean one, and that he looks for help from his readers in the improving of the book. As an inducement to such to send in to him corrections and additions, he offers to send free a copy of the next edition to all those who forward him 200 useful corrections or additions to the present issue. We have looked through the vocabulary very carefully, and have failed to find any very serious errors. In one place *exergue* is given as an English word. We do not remember to have met with it in practice. We propose to use this vocabulary regularly, and hope to be amongst those able to suggest the requisite number of improvements to entitle us to an issue of the next edition. This little volume, which consists of only some 320 pages, should find a place on the desks of all electrical engineers.

FORTHCOMING EVENTS.

FRIDAY, DEC. 14.

Institution of Mechanical Engineers.—At 8 p.m., ordinary general meeting, Sir Wm. H. White, F.R.S., in the chair. Discussion on Mr. Herbert A. Humphrey's paper on "Power-Gas and Large Gas-Engines for Central Stations."

Institution of Engineers and Shipbuilders.—General meeting in Newcastle-upon-Tyne.

Institution of Junior Engineers.—At 8 p.m., meeting, at Westminster Palace Hotel. Paper, "The Metallurgy of Tin," by Mr. J. H. Davy James.

Physical Society of London.—At 5 p.m., meeting, at Royal College of Science (by invitation of Prof. Rücker). The papers to be read are: "Electric Inertia" and "The Effect of Inertia on Electric Currents in a Rotating Sphere," by Prof. A. Schuster, F.R.S.; "Exhibition and Description of a Quartz-Thread Gravity Balance," by Prof. R. Threlfall, F.R.S.; "On the Theory of Magnetic Disturbances by Earth Currents," by Prof. A. W. Rücker, F.R.S.; "Notes on the Practical Application of the Theory of Magnetic Disturbances by Earth Currents," by Dr. R. T. Glazebrook, F.R.S.; "The New Physical Laboratories of the Royal College of Science," by Prof. A. W. Rücker, F.R.S.; and "Exhibition of a Set of Half-Seconds Pendulums," by Mr. W. Watson. Council meeting at 4 p.m.

Faradian Club.—At 8 p.m., club dinner, at Hotel Florence.

SATURDAY, DEC. 15.

Glasgow and West of Scotland Technical College Scientific Society.—At 7.30 p.m., ordinary meeting. Paper on "Technical Colleges in Germany," by Prof. A. MacLay, B.Sc.

North-East Coast Institution.—At 8 p.m., ordinary meeting at Newcastle-upon-Tyne.

Electrical Engineers Volunteers.—At 6.30 p.m., dinner to the South African contingent at the Trocadero Restaurant.

MONDAY, DEC. 17.

Society of Arts.—At 8 p.m., Cantor lecture on "Electric Oscillations and Electric Waves," by Prof. J. A. Fleming, F.R.S.

Electrical Engineers Volunteers.—Dinner to the South African contingent at the Prince's Restaurant, under the presidency of Prof. Perry.

TUESDAY, DEC. 18.

Electrical Engineers Volunteers.—Reception of the South African contingent by the Institution of Electrical Engineers at Covent Garden Opera House, at 8 p.m.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. The papers to be further discussed are "The Signalling on the Waterloo and City Railway" and "Note on the Signalling of Outlying Siding Connections," by Mr. Alfred W. Szlumper, and "Signalling on the Liverpool Overhead Railway," by Mr. Stephen B. Cottrell. Time permitting, the following papers will be read: "Glasgow Bridge," by Mr. B. H. Blyth; "Railway Bridge over the Fitzroy River at Rockhampton, Queensland," by Mr. W. J. Doak; and "The Niagara Falls and Clifton Steel Arch Bridge," by Mr. L. L. Buck.

WEDNESDAY, DEC. 19.

Royal Meteorological Society.—Ordinary meeting at the Institution of Civil Engineers at 7.30 p.m. Following papers will be read: "The Seasonal Rainfall of the British Isles," by Mr. Henry Mellish; and "A Review of Past Severe Winters in England, with Deductions therefrom," by Mr. Albert E. Watson.

THURSDAY, DEC. 20.

Institution of Electrical Engineers.—At 8 p.m., ordinary meeting. Lecture by Lieut.-Colonel Crompton, E.E. (R.E.), on "The Electrical Engineers (Royal Engineers) in South Africa."

Institution of Electrical Engineers (Dublin Section).—At 7.30 p.m., ordinary meeting in the University College, when a paper will be read by the Right Rev. Monsignor Molloy, D.D., D.Sc., on "Electric Currents of High Tension and Great Frequency, with Suggestions as to the Possible Electric Light of the Future."

FRIDAY, DEC. 21.

Institution of Civil Engineers.—At 8 p.m., students' meeting, Prof. Alex. B. W. Kennedy, F.R.S., in the chair. Paper on "The Use of Geometrical Methods in Investigating Mechanical Problems," by Mr. C. E. Inglis.

ROYAL INSTITUTION OF GREAT BRITAIN.

We have received a notice of the various meetings and lectures arranged by this institution for the first three months of the New Year. Weekly meetings are to be held on Friday evenings, beginning on Jan. 18, when Prof. Dewar will read a paper on "Gases at the Beginning and End of the Century." On Feb. 1 "Electric Waves," by the

Digitized by Google

Right Rev. Monsignor Molloy, will be discussed, while on the following Friday evening Prof. G. H. Bryan will bring forward a paper on "History and Progress of Aerial Locomotion." At the succeeding weekly meetings respectively up to March 1 the following papers will be read and discussed: "The Existence of Bodies Smaller than Atoms," by Prof. J. J. Thomson; "Metals as Fuels," by Sir W. Roberts-Austen, K.C.B.; "Enamels," by Mr. Henry H. Cunynghame, C.B.; and "Vitrified Quartz" (with experimental illustrations), by Mr. W. A. Shenstone. The lecture arrangements are well conceived, and include six at Christmas time by Sir Robert Ball "On Great Chapters from the Book of Nature." This course of lectures has been specially arranged to illustrate the bearing of modern astronomical discovery on Laplace's famous doctrine of the evolution of the sun and the moon, the earth and the planets. They will no doubt prove extremely interesting, and a large number of members of the institution and their friends are expected to attend. Among the other lectures to be given during the months of January, February, and March in the New Year are: "First Principles and Modern Illustrations," by Prof. J. A. Ewing; "The Cell as the Unit of Life," by Mr. Allan Macfadyen; "The Government and People of China," by Prof. R. K. Douglas; and "Sound and Vibrations," by the Right Hon. Lord Rayleigh.

POLYPHASE ELECTRIC TRACTION.*

BY PROF. C. A. CARUS-WILSON.

PART I.—THE POLYPHASE SYSTEM.

(Continued from page 808.)

Influence of the Starting Period.—From what has been said above, it might appear that the best results on a line such as that from Burgdorf to Thun would be obtained if the track were absolutely level, but this is not the case, since the motors have to be able to exert an abnormal effort in order to start the train, and this effort may be utilised in mounting a grade. Thus the maximum permissible grade depends upon the effort required to start. The ability of polyphase motors to accelerate, and their economy in so doing, are thus matters of importance, and the author has therefore made a number of tests on the Burgdorf Railway with a view to obtaining definite information on these points. An account of the tests is given later in this paper. Some of the results will be quoted here. Allowing 94 per cent. as the efficiency of the gearing at full load, the actual horizontal effort of the motorcars on the Burgdorf Railway, at 60 kw. input, is 3,500lb., from which has to be deducted the axle and track resistance of the motorcar itself; taking this at 15lb. per ton of load, for both motorcars and trailers we find that a single 32-ton motorcar will get up full speed, 24·2 miles per hour, in 26 seconds. The time observed in the tests was 30 seconds. The addition of one trailer will increase the time of getting up speed to 38 seconds. Two trailers should, by calculation, take 51 seconds—the test gave 57; three trailers should take 67 seconds—the test gave 71. Five trailers would take 106 seconds to get up speed. The discrepancy between calculation and test is probably due to the resistance to motion having been taken too small. In Table I. are given the number of trailers which can be drawn up different grades by one motorcar; also the corresponding acceleration with full load on a level, and the difference of time due to starting with maximum load as compared with the motorcar only. It will be seen that as the maximum grade is reduced the maximum possible load is increased, but at the expense of a considerable increase in the time lost in starting. Thus five trailers could be hauled up a grade of 1 in 100, but nine minutes would be lost in starting. This would probably be inadmissible, in view of the necessity of making connections with the main lines. If five minutes is fixed as the maximum permissible starting delay, a load

variation of three trailers could be dealt with, and this would mean a maximum grade of 1 in 62. In general, the maximum permissible starting delay should be fixed first; this determines the number of trailers, and this again the maximum grade. The fewer the stops, the larger will be the number of trailers, and the smaller will be the maximum grade. In considering the application of electricity to existing railroads, the grades and station intervals are of course fixed. The average station interval in this country is probably greater than that on the Burgdorf Railway, which is 1¾ miles, and the grades would not be so steep. If one assumed three miles as the average station interval, and 1 in 100 as the maximum grade on a line 25 miles long, a motorcar with an electrical equipment of 250 h.p. could haul a maximum of five trailers, or a total train weight of 92 tons, with a time difference of only five minutes between minimum and maximum load.

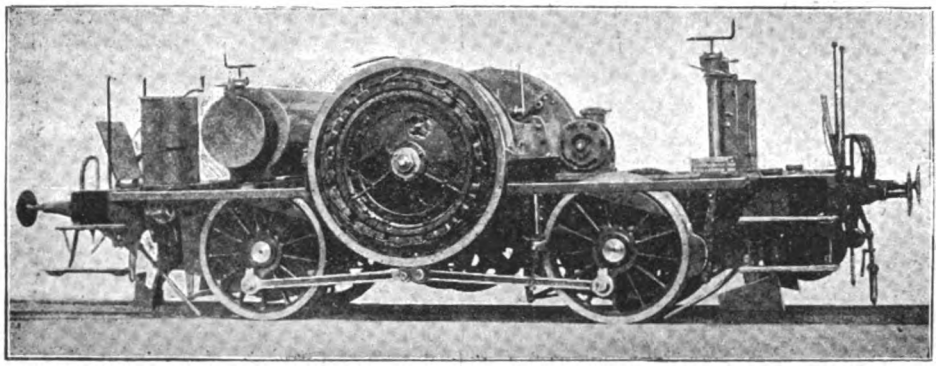

FIG. 10.—Locomotive with Cab Removed.

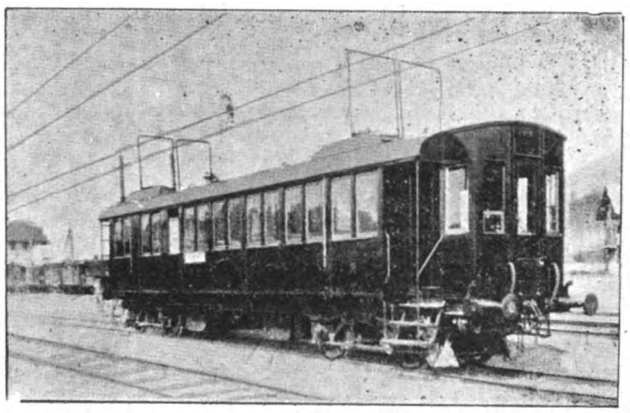

FIG. 11.—Motor Car.

The Goods Traffic.—On the Burgdorf Railway the goods traffic is hauled by locomotives specially designed for the purpose (as shown in Fig. 10), each of 300 h.p. These can haul a total maximum train weight of 50 tons at full speed up the steepest grade of 1 in 40. Details of the motors are given in Figs. 6, 7, 8, and 9. The locomotive itself, weighing nearly 30 tons, leaves only 20 tons for the weight of the train. Hence it has been found necessary to reduce the speed of the locomotive by gearing (see Fig. 9) so that they can run at half speed, and thus draw loads of 70 tons up the steepest inclines, the total train weight then being 100 tons. The time schedule of the goods trains is shown in Fig. 5. A reference to Table I. shows that if the steepest

grade had been 1 in 100 instead of 1 in 40, as at present, the same locomotive could either (1) carry a train of 100 tons at full speed, or (2) a train of 200 tons at half speed. The influence of the existing grades on the carrying power of the locomotives has already baen found to be a serious drawback. It may, however, be questioned if it is wise to use locomotives for hauling goods on such a line, since their use means so large a percentage of deadweight. The motorcars weigh about the same as the locomotives, carry 66 passengers, and can haul 60 tons behind them up a grade of 1 in 100. Supposing the average passenger load to be one motorcar and two trailers, making 56 tons, there remain 36 tons which might be made up by goods. Since there are 12 trains per day one way, the motorcars have a goods carrying capacity of 430 tons, or six times that of the existing locomotives. It would seem, therefore, that there is much to be said in favour of combining goods and passenger traffic on such a railway.

PART II.—ACCELERATION TESTS ON THE BURGDORF RAILWAY

In September, 1899, a series of tests were carried out at Konolfingen under the author's direction. The tests, which had to be made during the intervals between the passing of the regular traffic, were conducted on a motorcar to which trailers could be attached. The method of conducting a test was as follows: One of the engineers of the line took charge of the controlling apparatus, and acted as motorman. In the forward vestibule an assistant gave the time from a stop-watch to an observer, who noted the ammeter reading at each instant. In the rear vestibule a second assistant gave the time from a stop-watch, while one observer noted the voltmeter reading, and another took the reading of a speed indicator. Two men were told off to keep a look-out and announce points passed on the track, such as grade posts, etc. The speed indicator made a continuous automatic record of the speed, which was detached and numbered after each test. The motorman signalled the start, at the same moment throwing over the controller so as to give the motors the maximum current, which was maintained constant as long as possible. The readings of all instruments were taken at five-second intervals from the moment of starting, and one voltmeter reading was taken immediately before starting. Each observer recorded his own observations, and filled in those of the other observers after every test. The car was allowed to proceed for some distance after full speed had been reached; the current was then cut off, the brakes

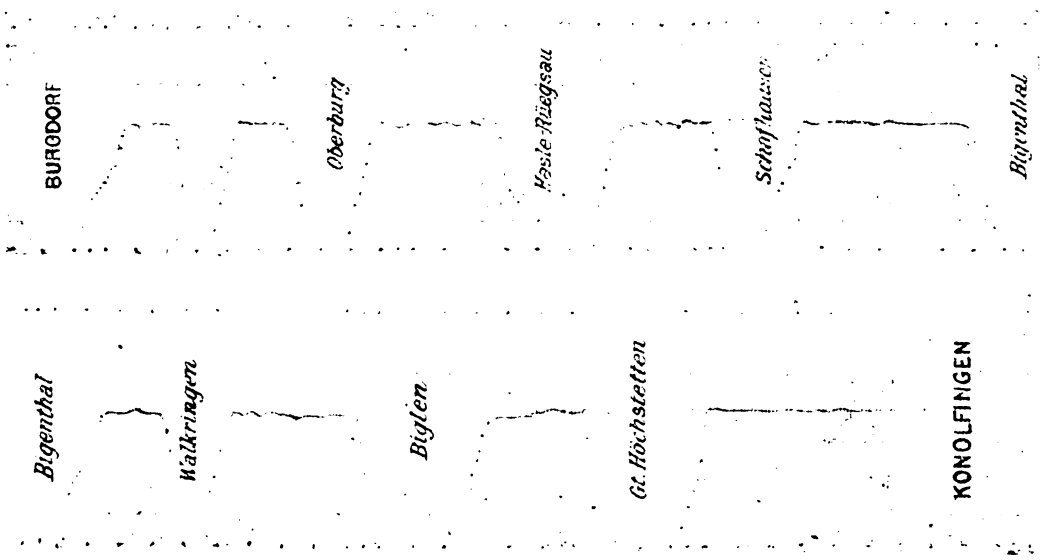

FIG. 19.—Full Size Automatic Speed Record taken on a Motorcar between Burgdorf and Konolfingen

put on, and the car brought to a standstill. Three sets of experiments were made: (1) with the motorcar only; (2) with the motorcar and two trailers; (3) with the motorcar and three trailers.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS.

On Thursday evening week the adjourned discussion on the paper by Mr. W. E. Langdon "On the Supersession of the Steam by the Electric Locomotive," was concluded. Prof. John Perry, president, was in the chair.

Mr. Robert Hammond thought they must all be struck on reading this most valuable and important paper by Mr. Langdon by the immense and new field which was opening out for the young as well as for the old electrical engineer. With regard to the question of lighting, it was a matter of astonishment that there was still a gaslight in existence, but in the near future there was no doubt that electricity would come in touch with every industry in the land. They had now a most painstaking and valuable paper before them, pointing out one great industry—viz., the supersession of steam by electric locomotives. There hardly seemed to be a more happier scheme than that proposed by Mr. Langdon. The paper did not deal in generalities, for the author not only said that in his opinion the thing was possible, but he showed how it could be carried out. It was clearly demonstrated that there would be a saving of over a quarter of a million a year in working expenses by the conversion of the section of the line between St. Pancras and Bedford from steam to electric power. The two main points for consideration were, first, whether the plan of running full-guage railways by electricity was feasible, and secondly, whether the estimates prepared by the author were sound. Mr. Hammond thought they might unhesitatingly let it go forth to the world as the opinion of that Institution that the plan suggested was feasible, and, further, that it appeared from the data furnished them that full-gauge railways could be run by electricity. It was actually being done in Germany at the present time on the Burgdorf-Thun line. The railway was 25 miles long, the primary voltage being 5,000 volts and the secondary 750 volts. On another line in course of construction in Italy by Ganz and Co., of Budapest, the extraordinary plan was being put into execution of having a primary voltage of 20,000 volts and a secondary of 3,000. With reference to the question of sub-stations, they must remember that in England coal could be bought at 7s 11½d. a ton, which could easily be carried to the point desired, whereas abroad there was not this facility. This favoured the views of Mr. Robinson on the advantage of several generating stations along the line of route.

Prof. George Forbes's criticism amounted to this: That this was hardly a paper to be brought before that Institution, being of too general a character. If Mr. Langdon had read his paper before a more public audience, such as at the Society of Arts, it would have deserved unqualified approval as directing the attention of the people to a question which had been engaging the consideration of engineers for a large number of years. The different methods in which the work could be carried out had not been considered by the author, nor had the details been accurately gone into. Prof. Forbes agreed, on the question of expense, that a stationary engine used less coal than a locomotive engine. He had paid considerable attention to the feasibility of working the Nile railways by electricity, and the conclusion he arrived was that, as a rule, electric locomotion would be cheaper than steam up to a distance of 40 or 50 miles from the power station. In Mr. Langdon's paper there was hardly a single item which would seem to be the right thing for his purpose. The total expenditure in respect of conductors had been put at £70,000, but there was no doubt that the cost would be very much in excess of that figure. He calculated it out at £330,000 with the voltage mentioned by Mr. Langdon.

Mr. F. Hudleston, chief construction engineer for the Central London Railway, confined himself to the question of coal consumption. Mr. Langdon had underestimated the work necessary to be done on a heavy railway. The section of line selected was hilly, with curves, and yet the author of this interesting paper said that it was practicable to haul a goods train with an average resistance of only 5½lb. per ton. As a matter of fact, an ordinary goods train along a level would require quite 10lb. per ton. On an average the coal necessary for a passenger train was 36lb. per train mile, for a goods train 53lb., and for a train laden with minerals 62lb. This figure might be reduced to 4lb. per ton mile on the Central London Railway. It must be remembered, however, that the switchback system on the Central London saved about 30 per cent. of the total energy required to accelerate the train. On the underground railway in London the average consumption of coal was from 32lb. to 36lb. per train mile. The trains weighed from 135 to 140 tons. This came out at ·25lb. of coal per ton-mile. Of course, in making this comparison, it must be remembered that the locomotives used the best steam coal, whereas in the central stations slack was used. Mr. Hudleston then expressed the opinion that the coal economy suggested was not proved in the least. With their present knowledge of electricity and steam, he did not see how it was possible to arrive at the author's result. With the exception of the coal consumption question, all the other matters in the paper were satisfactory.

Mr. A. A. Campbell Swinton could not agree with Prof. Forbes that the paper was not suitable for that Institution. It was the most interesting and suggestive paper they had had for a very long time. About a year ago he happened to have been looking into the question of expenditure of a contemplated electric line about 50 miles in length, and the conclusion he arrived at was that the total cost of equipment would be just a little more than that named by Mr. Langdon. But there the resemblance ceased. He could not understand how the author was going to do what was necessary in the way of cables, trolley wire, etc., for the sum of £140,000. A slight saving in the cost of the trolley wires would be made if a three-phase system at 750 volts were employed, as on the Burgdorf-Thun Railway. The line now being constructed in Italy was to work with 3,000 volts on the trolley wires, which would do much to keep down the first cost if the Board of Trade objections could be got over. The use of three-phase would also do away with the necessity of having rotary transformers in the sub-stations, and the necessary attendance to look after them. A very important question raised by the discussion was whether there was an economy in building a very large station. There undoubtedly was, and the larger the station the more economical it was. A parliamentary committee had been persuaded to take this view, which was certainly correct. If stations were to be placed about every mile all along the lines, how was a constant load to be got? Each station would be working for five minutes, and then it would have to be shut down for an hour, entailing unnecessary labour. Economy could only be attained by having one station to work over one length of line.

Mr. A. H. Walton thought that everything was not just as it should be in this paper. Mr. Langdon had put it before the Institution in a very broad manner, and his figures as regarded the traction efforts required were put far too low. He thought that the lowest record yet attained was 40 watt-hours per ton-mile. If one took the formulæ in Molesworth and worked them out, the result arrived at was 44·8. With reference to the author's statement that the coal consumption would be about 3lb. per kilowatt-hour, it was impossible to agree. If they got 4·5lb. to 5lb. they ought to be satisfied; 3lb. per kilowatt-hour had never been accomplished yet. On the Central London Railway, they had been told, the coal consumption was 5·9lb. per kilowatt-hour. But it was impossible to make fair comparisons by weight, because there was such a difference in the quality of coal; comparisons of cost of coal per unit would be more fair. He thought that on the question of leakage Mr. Langdon had been too liberal, because a 2½ per cent. leakage was very excessive, as it showed an absurdly low insulation resistance.

Mr. A. J. Lawson said the author had done some injustice to his case by taking too low a figure for coal consumption. He had also assumed too low figures for the efficiency of his plant. There should be no difficulty in getting motors of 90 per cent. efficiency, or in obtaining rotary converters of 93 per cent. and static transformers of 97 per cent. efficiency. In fact, with Mr. Langdon's arrangements, he thought an over-all efficiency of 71·35 per cent. could be obtained, whereas, if three-phase motors were used, this might be still further increased to 75 per cent. by the elimination of the rotary converters. As Mr. Hammond had said, a high-tension three-phase transmission had been in fairly successful use in Germany, and a higher voltage would shortly be put into use elsewhere. From this information was to be gained, and he thought it would do away with the suggestion of having many stations at certain intervals along the line. If generating stations were used at distances of about 10 miles apart, it would mean much additional labour and cost, because they would be so unequally loaded at different times.

Mr. Alexander Siemens pointed out that the discussion had entirely branched off into details. His opinion was that with a busy suburban line, with more than 12 trains per hour, electricity was cheaper than steam, but for main lines it was a question if that were so. Mr. Langdon had proposed that the railways should be connected in sections of 50 miles. Was he going to change engines at the end of these distances? For the long main-line trains, where only a few trains were run a day, the electric system would not be economic.

Major P. Cardew said that one important thing to notice in the tables given in this very interesting paper was the extremely short mileage made by each locomotive in one week. On the London and North-Western Railway one locomotive only ran 314 miles per week. The wages table came out very high for this reason, and there was certainly room for economy in that department. Mr. Langdon had dealt with the traffic as it existed, and had not taken into consideration the fact that with electrical working a more frequent service of trains would result. Major Cardew gave it as his opinion that a high-tension three phase transmission was an arrangement of very considerable economy. The arrangement proposed by Ganz and Co. for connecting the motors in series when starting and stopping to get practically half speed was very valuable. It was also worthy of note that in certain of the Continental towns electric locomotives driven by accumulators were being used with success.

Mr. E. Segundo thought that Mr. Langdon had attacked a question of national importance, and had acquitted himself in a manner worthy of the best traditions of that Institution. But as to the question of coal consumption, the figures given were not quite correct. He had worked out the average consumption, and he found it was more like 4·5lb. per kilowatt-hour than 3lb. The author had not suggested how freight traffic was to be dealt with. The tendency now was to increase the weight and length of freight trains and run them at longer intervals. But he believed that the electrical locomotive need only be half the weight of the steam locomotive, because all the weight came on driving wheels.

Mr. F. Sprague said they were all interested in the problem of the conversion of steam railways into electric. His opinion was

Digitized by Google

that the conversion would not be carried out, as suggested in the paper, by having electric locomotives constructed on the lines of the steam locomotives. In connection with rating of dynamos, the makers prescribed certain limits of heating which would not be surpassed if the dynamos were run continuously. On the other hand, the rating of a railway motor was done on most arbitrary lines with no such limit. For instance, a 150 h.p. railway motor would only be able to take 35 kw., or 47 h.p., from the mains continuously without rising more than 75deg. in temperature. The design of motor for the railway locomotive was restricted on all sides by the conditions of the very small space available under the cars, etc., and, in his opinion, it was quite impossible to build electric locomotives to pull the trains on the great railways. What was required was a complete change in the method of service, with electric motors of small power distributed throughout the train and controlled from one end. If the conversion were effected he did not believe there would be any saving of coal, but an improved service would be got at a higher speed.

Prof. Carus-Wilson was of opinion that it was not on the main steam lines that the electric locomotive would first be successful in this country. If anywhere, it would be on the branch lines—for these reasons: first of all, that the branch lines at the present time were the unprofitable part of any railway system; secondly, that it was the branch lines which were mainly responsible for the unpunctuality of trains; and, thirdly, that in consequence of the infrequent service of trains the branch lines were being menaced by the tramways systems. He estimated that on the branch lines of the Midland Railway which radiate out of Bedford the number of penny passengers required per mile in order for a profit to be made, with a service of six trains each way, was 265 per day. His point was that in order to make a profit with 24 trains per day and steam locomotive, you would want an increase in penny-a mile passengers of 75 per cent. A 60 ton train on an average branch line, conducted in the cheapest way, could be run by electricity with much better results than by steam. If the Midland Railway were to run a train every half hour, instead of one every two hours, there could be no doubt that the necessary increase in passengers (say 30 per cent.) with electric driving could be obtained, and the demands of the public satisfied.

Mr. W. Langdon, in reply, said there was no doubt as to the applicability of electricity for all purposes, and the only question remaining was, whether it was more economical to run trains by electricity than by steam. He had been attacked for bringing the paper before that Institution, but it certainly appeared to him that the subject was one which mainly affected the Institution of Electrical Engineers, and perhaps no better body could be found in the kingdom to discuss its merits or demerits. The subject had been deal with by him in an abstract manner, and the purpose of the paper was to evolve, if possible, some result as to the economy or other advantages that might attend the use of electricity as supplied to the large railway services of this country. It seemed to him that there was a greater chance of its succeeding where there was most traffic, and it was for this reason that he selected the London and Bedford section of the Midland Railway. Mr. Mark Robinson had questioned whether it was desirable to work a section of line from a central station or from a number of local generating stations. What had escaped the attention of some of those who had taken part in this discussion was the fact that with a central station you were able to transfer the load from one section to another. The estimates given in his paper were not definite estimates. They were meant to show what might be advantageous results arising from electric systems. The question whether a line could be worked from a central station was one to be very carefully considered when the time came. With regard to the question of coal consumption, it had been stated that the estimate of 3lb. per kilowatt-hour was insufficient. Mr. Cuningham had said that 3·6lb. per kilowatt-hour had been obtained in Montreal, while the Hon. C. A. Parsons estimated that 2·5lb. was a fair figure. He had recently looked up some figures on the subject published in *Engineering*, from which he gathered that on the Metropolitan in Chicago there was a consumption of 1·75lb. At Boston it was 2·61lb., at Baltimore 3 23lb., and at Brooklyn 3lb. Again, some trials made on the Berlin trams had revealed the consumption of 2·1lb. of coal per kilowatt-hour when superheat was employed, and 2·3lb. with the use of ordinary steam. All he could say was that if ½lb. of coal per kilowatt-hour could be saved, it was very material. The case of drivers of locomotives had been mentioned by Colonel Crompton, who suggested that a less wage might be paid those employed to drive electric motors. The wages paid to drivers were undoubtedly a very heavy charge indeed, but he did not see how it was possible to have it modified unless the traffic arrangements were also modified. Then in regard to the repair and renewal of machinery, Colonel Crompton had said that the charges put down in respect of that matter were high. But if anything were ever done in the introduction of electricity for main lines, it would have to be of the simplest character. The gist of the whole question lay entirely in the manner in which the current was to be conveyed to the trains. If it could be arranged to be placed outside the rails carrying the vehicles, it would prove very much more satisfactory, and would tend in a greater degree to its adoption than if it had to be laid down between the rails. It had been said that no electric locomotive could be framed to take the place of a steam locomotive. But surely that was contrary to the opinion of nearly every engineer who had studied the subject.

The **Chairman** here called attention to the length of the proceedings, and

Mr. Langdon said he would conclude his remarks on the discussion in his written reply to the *Journal*.

INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting on Dec. 11, Mr. James Mansergh (president) in the chair, three papers were read, entitled "The Signalling on the Waterloo and City Railway" and "Note on Signalling Outlying Siding Connections," by Mr. A. W. Szlumper, M.I.C.E., and "Signalling on the Liverpool Overhead Railway," by Mr. S. B. Cottrell, M.I.C.E.

The Waterloo and City Railway, as previously described in the minutes of *Proceedings* of the institution (vol. cxxxix.), was an electrically-worked underground railway 1½ mile in length. It was a double line, in separate tunnels, with a station and accommodation for shunting the trains at each end. Trains ran every six minutes, the journey occupying about six minutes. There were two signal cabins, one at Waterloo and one at the City, the former containing 16 levers and the latter 18 levers. The line, however, was practically divided into two block sections by the provision of signals about half-way between the stations, such signals consisting of an electric lamp fixed to the wall of the tunnel, electrically controlled from both boxes and by clearance bars or treadles. In addition to the ordinary mechanical interlocking, the Sykes electric lock-and-block system had been largely introduced, and as a further safeguard "slipper bars" were fixed a short distance in front of the more important signals by means of which the current to the electric motors was automatically cut off should a train pass the 'slipper bar" when the signal was at danger. The "starting" signals at the stations had double arms, the upper one being a "right away" signal, the lower one being a "draw ahead" signal. Both these arms were worked by the same lever by means of a Sykes "electrical selector." The "stop" signals at the stations consisted of ordinary ground-discs, which were also provided for shunting movements. Treadles or fouling bars were extensively used; they consisted of an angle-bar about 35ft. in length, balanced on pivots and connected to a contact-making switch. In lieu of the ordinary repeaters, bells were fitted in the signal boxes which rang when any signal failed. This was effected by passing a wire through a series of signals by means of contact-makers on each signal and upon their corresponding lever in the signal box, terminating in a bell which started ringing should any contact be broken. Facing points were fitted with ordinary facing-point bolts, also Sykes electrical point detectors, one being fixed to each stock rail on a pair of points and connected to and working with the tongues. Both tongues had to be dead home before the selector was operative, and until then the point lever was locked by an electric lock. The block instruments used were Sykes lock and-b'ock instruments, which were electrically interlocked with the levers and signals. All the lights in the signals and discs consisted of 8-c.p. incandescent lamps in duplicate, and were repeated in the signal boxes by pilot lights.

The second paper described some modern methods of electrically controlling outlying siding connections. One system described was applicable to a railway where an electric lock-and block system was installed. The siding connection was controlled by a key, the removal of which from an instrument locked up all conflicting signals and broke down the block instruments until the key was returned. No outdoor signals at the siding were necessary. Another system described consisted of the provision of a ground box and outdoor signals at the siding, locking instruments being provided at both the section and siding boxes. When the siding was to be used, the switching in of the siding box locked up the starting signal at the section box by means of an electric lock, and released an electric lock on the siding signal, the switching out of the siding box restoring the section-box signals and instrument to their normal condition. A special feature of this scheme was electrically locking up the entrance to the siding box from the section box. Another system described consisted of the provision of a ground-box and of outdoor signals at the siding connection. When operations were to be carried out at the siding the box was switched in as a section box, and electric locks on the signals were released; during shunting operations the

Digitized by Google

siding box was treated as a section box, and when completed the box was switched out, and the signals again became electrically locked from the section box.

The third paper described the system of automatic electric signalling in use on the Liverpool Overhead Railway, which, originally promoted to facilitate passenger transit to and from the docks, had developed into a line nearly seven miles in length, and, in addition to fulfilling its original purpose, provided rapid access to Liverpool from two important suburbs, and by means of an electric tramcar system owned by the company from other suburbs. When the line had been originally constructed as a dock railway with many stations, automatic electric signals had been introduced in order to avoid the expense of men and maintenance, but with the extensions in the suburbs the automatic system had had to be supplemented at termini and junctions by ordinary mechanical signals. The intermediate stations were divided into 14 block sections; each block had a station at its commencement, and since the length of the blocks was short, each station was equipped with only four signals—viz, one home signal and one starting signal for each road, the starting signal being practically the distant signal for the station in advance. A train leaving a station passed the "breaking" contact, putting the starting signal to "danger"; it then passed the "making" contact, which pulled off the home signal of the station it had just left, and the starting signal of the station in the rear. The circuit between the making contact and the other signals was made through a switch fixed on the arm of the starting signal, so that should the latter fail to go to "danger," the circuit could not be completed, and the line behind would be blocked. The making and breaking contacts were actuated by a striking board fixed on the last coach, so that should a train break in two, the signals would not be operated. This automatic arrangement applied to all intermediate stations, and where the automatic system merged into mechanical, the alteration took place at the home signal in one direction, and at the advance starting signal in the other—that was, on the up road the advance starting signal was the first automatic signal, and on approaching the termini the distant signal was the first mechanical one. The current for working the signals was supplied from accumulators at 50 volts pressure; two sets of 27 cells were situated at each station, and these were charged in series from the generating station. These accumulators also provided light to the stations. The expenditure of electric energy in current was very small. Each station comprised four signals, each worked with a lowering current of five amperes at 40 volts, and with a holding current of 0·25 ampere at 40 volts. With a three-minute service for 20 hours a day each signal would be lowered 400 times, requiring, therefore, 2,000 ampere-seconds, or, say, 0·5 ampere-hour, per signal per day. The entire station would require 80 watt-hours per day, and the total system 1,040 watt-hours. This, however, did not include the holding-off currents. Assuming each signal to be held down 1½ minute, it would be down 600 minutes per day, requiring 150 ampere-minutes, or 2·5 ampere-hours, or five times as much as for lowering. In the first few months there had been occasions of signals failing to go to "danger," but experience enabled such failures to be eliminated, and reduced the number of other failures, which now amounted to an average of only 1 in 14,156,857 operations.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

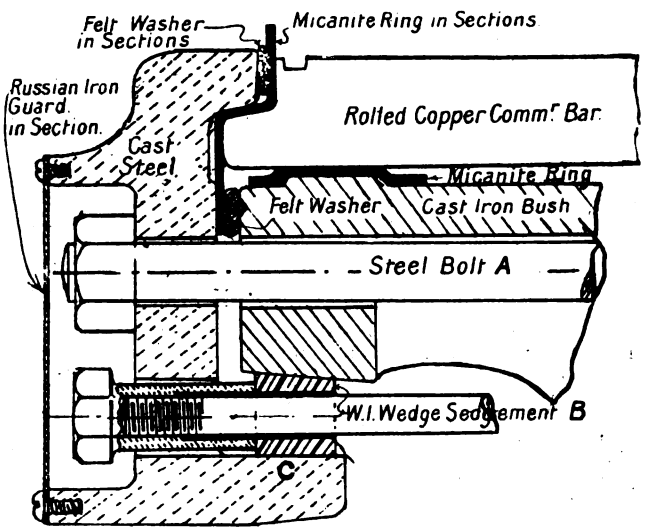
333. How can the Thomson-Houston and similar meters be adjusted without either breaking the seals on the controlling magnets or altering the position of the coils?—C. H. K.

334. An output of 2,500 h.p. has to be transmitted from a power station to a chemical works two miles away. The load is a continuous one night and day. The works generate three-phase alternating current, with 2,000 volts between adjacent wires, and the pressure at the chemical works is required to be 200 volts. Investigate what is the most economical voltage for transmission with underground cables.—P. T.

ANSWERS.

Question No. 327.—The commutators for large direct-current generators are frequently required by the engineer's specification to be assembled in such a manner that a portion of the bars may be removed without disturbing the remainder. How is this best accomplished, particularly with reference to the end insulating rings, which presumably would be in sections and would require skilful jointing?

Best Answer to No. 327 (*awarded* 10*s.*).—A design of commutator to fulfil these conditions is shown herewith.



The end ring is divided into six, eight, twelve, or more segments, the number depending on the diameter of the commutator. Through each segment two steel bolts, A, pass, also two adjusting rods, B. The bolts are prevented from turning by a recess for the heads in the back ring. The adjusting rods are screwed and riveted into the wedges at the inside end. The centrifugal strain is taken on the lip, C. The bars rest on a micanite ring moulded on to the commutator bush. The micanite end ring is made in a similar number of segments to the outer ring, the joints being made as shown in the accompanying

diagram. These rings are so placed so as to have the joints in them and the outer ring "staggered." A groove is turned in the bush to grip a felt ring, which prevents copper dust, etc., getting underneath the bars. To remove any bars the wedges are slackened in the two segments covering the section of micanite ring in front of the faulty bars, and then the nuts on the main bolts can be taken off and the segments removed. If the joint in the micanite ring is made coincident with the end ring joint, only one segment would have to be disturbed to get at the bars, but there would be a greater danger of breakdown through dust working through the joints in the micanite ring.—M. N.

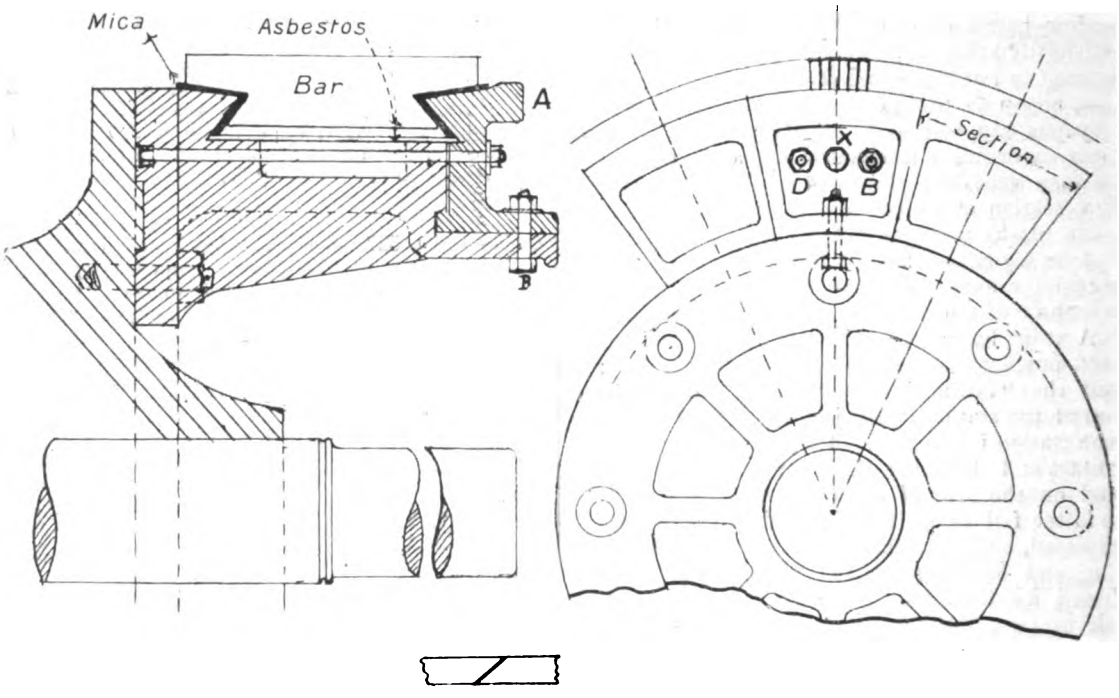
Answer to No. 327 *(awarded* 5*s.).*—The commutators for large direct-current dynamos are assembled as shown in the accompanying sketches (Figs. 1, 2, and 3). Fig. 1 is a sectional elevation of the commutator tube, which is made of cast steel and secured to the spider by eight studs, as shown. It is insulated on the body with asbestos. The end ring, A, is made in segments, each fitted with two bolts to tighten up the bars, while a bolt, B, in each segment is shown to tighten it down on the periphery of the tube.



FIGS. 1, 2, AND 3.

To take a section out, the bolt, B, and the nuts, D and E, are removed, a forcing screw is put in at X, which on screwing up forces the section out, leaving the mica insulating intact. To get the bars out, this ring, which is usually made solid, has to be carefully cut in the form of a scarfe (Fig. 3). It is a comparatively easy matter to take a section of bars out, but a job of some difficulty to get the bars down flush with the others when new mica has been put between them. In the event of the scarfe in the mica ring being damaged, it must be patched up with mica of exactly the same thickness. Neglect of this precaution will cause the bars opposite the thickest part to be tight, and those at the thinnest part to be slack.—K. V. R.

Question No. 328.—What should be a fair coal consumption for a 10-hour day with the following output—600 amperes 105 volts steady over the 10 hours. Engine is high-speed three-crank tandem compound single-acting, with variable expansion governor (rated as 127 b.h.p. with 100lb. steam pressure), coupled direct to 80-kw. dynamo. Steam is kept at 10lb. square inch higher than is registered by gauge (75lb. square inch) on engine side of governor valve, with 600 amperes. This is Lancashire boiler hot feed water.

Best Answer to No. 328 *(awarded* 10*s.).*—The combined set working at three-quarter full load is probably working at its most economical load, and from the particulars given we may reasonably assume a consumption of steam for the combined set (including, say, 10 per cent. loss in dynamo) of 28lb. per electrical horse-power. But the coal consumption depends chiefly upon the quality of the coal. Let us take the average Lancashire coal containing carbon 77·8 per cent., hydrogen 5·32, oxygen 9·4, sulphur 1·3, and ash and nitrogen 6·18 per cent. Now, the total heat of combustion of carbon is 14,500 B.T.U., and can, therefore, evaporate 15lb. of water at and from 212deg. F. The total heat of combustion of hydrogen is 62,032 B.T.U., and can, therefore, evaporate 64lb. of water at and from 212deg. F., but we must remember eight parts of oxygen by weight unite with one of hydrogen to form water, which exists as such in the coal. Sulphur exists only in small quantities, and its heat of combustion is only 4,000 B.T.U.

Now, the evaporative power of 1lb. of the above coal

$$= 15\left\{ \cdot 778 + 4 \cdot 28 \left(\cdot 0532 - \frac{\cdot 094}{8} \right) \right\}$$

$$= 14 \cdot 325\text{lb. of water at and from } 212\text{deg.}$$

At 85lb. pressure we require an additional 3·5 per cent. of heat units. And owing to imperfect combustion, radiation from boiler pipes, etc., and other causes, a Lancashire boiler seldom exceeds 50 per cent. of the theoretical evaporation. We will take 7lb. of water as the approximate evaporation of 1lb. of the above coal at 85lb. boiler pressure. Then

$$630 \text{ Board of Trade units} \times 1 \cdot 34 = 844 \text{ e.h.p.}$$

$$\frac{844 \times 28}{7} = 3{,}376\text{lb.} = 30 \cdot 1\text{cwt. coal.}$$

We must allow for initial raising of steam—*i.e.*, losses during the 14 hours' standing—say 1·5cwt. So that we have as a fair everyday working consumption 31·6, or, say, 32cwt. of above coal per day.

On trial runs or tests far better results could be obtained. Taking the 32cwt. = 3,584lb. ÷ 630 = 5·68lb. coal per Board of Trade unit, and 2,240 ÷ 5·68 = 394·3 Board of Trade units per ton of coal, a fair average under the conditions mentioned. The feed pump I suppose to be electrically driven. Usually in small generating stations most of the preventable waste takes place in the boiler-house, but it must not be forgotten we often pay heavily for dirty water—in fact, at coal price.—F. R. S.

[N.B.—Will the writer of this answer kindly forward his address.—ED. *E. E.*]

Answer to No. 328 (*awarded* 5*s.*).—An engine of the type described, running under the conditions given, will have a mechanical efficiency of 87 per cent., and will require 26lb. of steam per indicated horse-power hour. The efficiency of the 80-kw. dynamo at the 63-kw. load will be, say, 91 per cent.; the combined efficiency of the set will then be 79 per cent.

The electrical horse-power is 600 × 105 ÷ 746 = 84·5.
The indicated horse-power is 84·5 × 100 ÷ 79 = 107.

Steam required by engine is 107 × 26 = 2,780lb. per hour. An addition must be made to this quantity for steam required for the boiler feed pump and for loss by condensation in pipes. The amount varies widely, and depends to a great extent upon the suitability of the plant in use for the work performed.

For instance, if the steam dynamo and boiler in question

Digitized by Google

form only one of a number of units at a central generating station, then it is possible that they are connected to a large steam main, and that the pump is large for the feed water required, when the condensation loss and pump steam will be a sensible proportion of the total, particularly if the engine is the only one running, say, on the day load. It is not stated in the question whether this is so, or whether the other extreme may be taken when the installation is complete and well proportioned, though small. It will only be possible to estimate this quantity, and if it is taken as 10 per cent. of the engine steam will represent a fair average. The steam required per hour will now be

$$2{,}780 + 278 = 3{,}058\text{lb.}$$

A Lancashire boiler with hot feed under ordinary working conditions, supplying this quantity of steam, will evaporate 8lb. of water per pound of best steam coal, inclusive of that required for banking fires at end of day's run. The coal required per 10-hour run will be

$$\frac{3{,}058 \times 10}{8} = 3{,}822{\cdot}5,$$

or a little more than 34cwt.

If the engine is condensing, then 15 per cent. may be deducted, reducing the coal consumption to 29cwt. This result cannot be considered economical, although as good as may be expected under the circumstances. It is a good illustration of the loss of economy due to the use of low-pressure steam in a class of engine which will give good results when using high-pressure steam and running at or nearly its full load.—E. G. B.

Answer to No. 328 (*awarded* 5*s.*).—The coal consumption under the conditions mentioned in the question would depend on the following: (1) quality of coal used; (2) efficiency of boiler; (3) temperature of feed water; (4) efficiency of engine; (5) efficiency of dynamo. Assuming that the coal used is of average quality, the boiler having the ratio of grate area to heating surface which is usually allowed in standard Lancashire boilers, and the feed water to enter the boiler at, say, 180deg. F., the weight of water evaporated per pound of coal ought to be not less than 8lb. The mechanical efficiency of the combined engine and dynamo $\left(\frac{\text{E.H.P.}}{\text{I.H.P.}}\right)$ would probably be about 85 per cent. for an engine of the type in question coupled to a dynamo of good design and make. The dynamo, however, would be working at only slightly over three-fourths of its rated power, as also would the engine, while the steam pressure at which the engine is intended to work (for full power) is not maintained. Under these circumstances it would probably be safer to assume an over-all efficiency of only 80 per cent. The actual load of the dynamo is 63 kw., or 84·5 e.h.p., which at 80 per cent. efficiency means 105·6 i.h.p., and multiplied by 10 gives 1,056 horse-power hours. The steam consumption per indicated horse-power per hour is about 24lb. In a good engine of the type mentioned in the question, and taking this figure the total coal used would be

$$1{,}056 \times 24 = \frac{25{,}344}{8} = 3{,}168\text{lb.}$$

This does not make allowance, however, for the fall in pressure between the boiler and the engine, which is 10lb. in 85lb., or, say, 12 per cent. Making this deduction, we have total coal used $= 3{,}168 \times \frac{85}{75} = 3{,}590\text{lb.} = 1{\cdot}60$ tons.

The above result would be a very fair one for the plant in question for a day of 10 hours; but, of course, there would be the coal used for boiler feeding purposes (feed pump or injector) to take into account over and above that for the engine.—R. M. W.

LIGHT RAILWAYS.

We understand that the difficulties which for the past three years have stopped progress in connection with the Cromarty and Dingwall light railway are on the point of being surmounted.

The Salisbury Town Council are urging the Great Western Railway Company to proceed with their application for an extension of the time within which they were to construct the Salisbury and Pewsey light railway.

The Tramways Committee of the Birkenhead Corporation are considering the Wirral light railway scheme, by which it is intended to unite the borough of Birkenhead with the districts of Upton, Greasby, Frankby, Caldy, West Kirby, Hoylake, Meols, Leasowe, and Wallasey.

The Bridgwater Rural District Council have passed a resolution heartily approving of the Stogursey light railway order which has just been issued by the Commissioners.

A committee of St. Combs and Charlestown and other villages has been formed with a view of approaching the parties who at present seem to be delaying the Fraserburgh and St. Combs light railway scheme.

The Batley Corporation have lodged with the Board of Trade objections to the confirmation of the Spen Valley light railways and Spen Valley light railways (extensions) orders.

Plans of the proposed light railway from Turton to Darwen have been referred to the engineer of the Bolton Corporation.

The draft order of the Nidd Valley light railway has been issued by the Commissioners.

Plans and sections have been deposited with Mr. John Berry, clerk to the Clifton Parish Council, of a proposed light railway through the township which the Barton Rural Council have given notice to apply to the Light Railway Commissioners for powers to construct.

In connection with the proposed light railway for Hemsworth and Ackworth, the Light Railway Commissioners have suggested that a level crossing should be utilised across the Wakefield and Doncaster main road, but the Hemsworth Council are opposing such action.

NEW COMPANIES.

The following new companies have been registered:

Crown Electric Heating Syndicate, Limited.—Capital, £5,000. Object: to carry on the business of electricians, electric and general engineers, suppliers of electricity, etc.

United Railway and Trading Company, Limited.—Capital, £500,000. Object: to adopt an agreement with E. A. Hopkins to construct and maintain telegraphs and other works in America and elsewhere, and generally to carry on the businesses of electricians, electric lighting, etc.

J. and E. Hall (1900), Limited.—Capital £250,000. Object: to acquire the business carried on by J. and E. Hall, Limited, at the Dartford Ironworks, Kent; to adopt an agreement with the said company and its liquidators; and to carry on the business of mechanical, marine, and electrical engineers, etc.

Gas and Mechanical Speciality Company, Limited.—Capital, £5,000. Object: to carry on the business of gas engineers, manufacturers of gas, electric, and other lighting appliances, etc.

J. Player and Son, Limited.—Capital, £1,500. Object: to acquire the business carried on at Coventry as J. Player and Son, and to carry on the business of watch, clock, scientific instrument, electric and cycle fittings manufacturers, etc.

British Electric Railways, Limited.—Capital, £100. Object: to carry on the construction and maintenance of electric and other railways and tramways, etc.

Holden Motor Patents Syndicate, Limited.—Capital, £10,000. Object: to carry on the business of vehicle builders, electricians, electrical and general engineers, etc.

Isidor Frankenburg, Limited—Capital, £250,000. We are informed by this company, with reference to our note in last week's issue, that this is their correct title, and that the capital is £250,000.

NEW COMMITTEES.

The following additional committees have been appointed:

BATLEY.—*Electric Lighting, Traction, and Tramways*: Councillor Hirst, chairman.

BERMONDSEY.—*Electric Lighting*: Aldermen Rodgers and Walker; Councillors Cox, Grace, Hole, Burtwell, Bessell, Moss, Collins, Manser, Martin, and Marner.

DONCASTER.—*Electric Lighting*: The Mayor (Councillor Theobald); Councillor Dowson (chairman); Aldermen Athron, Wainwright; Councillors Brightmore Manwaring, Bennett, Gyles, Halmshaw, Smith, Tovey, and Wightman.

HASLINGDEN.—*Electric Light, Refuse Destructor, and Tramway*: The whole of the Council; chairman, Councillor Worsley.

HAMMERSMITH.—*Electricity*: The Mayor (Councillor T. Chamberlen); Aldermen Glasier, Cramp, Pascall, Canon White; Councillors Bendon, Boarder, Davies, Edwards, Harris, Hooper, Lieut.-Colonel Hopkins, Johnson, Rutter, Tomes, and one other to be appointed.

OXFORD.—*Streets, Roads, and Lighting*: Councillor Kingerlee, chairman; Councillor Woodward, vice-chairman.

LEGAL INTELLIGENCE.

SMOKE NUISANCE SUMMONSES.

On Wednesday last the South London Electric Supply Corporation, Limited, were fined, in the Lambeth Police Court, £10 on each of 10 summonses and 10 guineas costs on the first summons, for causing a smoke nuisance at the works near Loughborough Junction The Town Clerk of Lambeth prosecuted. The magistrate had evidence before him that black smoke had issued from the shaft at the works of the company on 10 different days. It happened that the company had had careful notes taken as to the behaviour of their furnaces, and that in consequence they had direct evidence to the effect that there was no black smoke issuing from it at certain of the times alleged. On one of the days a directors' meeting was held, and the directors watched the shaft during the afternoon. Their evidence, however, was discarded by the magistrate. We hear that his decision is being appealed against, and we trust that the persecution of the company will in consequence be stopped. It will be remembered that the same magistrate recently stopped the company burning the refuse they were bound to take from the then vestry, and it is now rumoured that the new council will bring an action against the company for damages for the very breach of agreement they or their responsible predecessors caused.

CLAIM FOR ELECTRICAL WORK.

In the Westminster County Court on Friday last his Honour Judge Lumley Smith, Q.C., tried the case of Buchanan *v.* Bishop, in which the plaintiff, an electrical engineer, carrying on business at 68, Victoria-street, S.W., sued the defendant, a builder, to recover payment of an account in respect of electrical work done.

It appeared from the evidence of the **Plaintiff** that the defendant built a house for a Mr. Glenny, and his (plaintiff's) firm were employed to fix the wires for the electric installation. After the wiring was completed it became the duty of the defendant to fix the floorboards in various parts of the house, and in doing so he should have used screws, but instead of doing so his men drove long nails through the boards, with the result that they pierced the electric wires in several places and rendered it necessary to rejoint them.

Mr. Chas. Curwen, a member of plaintiff's firm, was called, and gave evidence to prove that the wires which had been fixed by his firm were punctured in many places owing to the negligent way in which the defendant's men did their work.

Plaintiff's foreman was called and gave similar evidence as to the damage.

For the defence **Mr. Wm. Bishop** was called, and said he built the house in question at Putney. He did not dispute that damage was done, but he thought it had been much exaggerated.

His Honour said that, judging from the evidence which had been put before him, he did not think the plaintiff had claimed a penny too much, therefore judgment would be for the amount claimed, with costs.

ARBITRATION.

Last week Major Cardew, as arbitrator, heard arguments in connection with the dispute between the Chloride Electric Storage Syndicate, Limited, and the Corporation of King's Lynn. The points at issue arose out of the installation of the storage batteries at the King's Lynn electricity works from the specification of Prof. Henry Robinson. We gather from the evidence, as reported in the King's Lynn newspapers, that one clause of the specification required the contractor to fill in a schedule of rates for the day work, and to include in the first tender the assumed number of years that would be required to erect the accumulators in question. It seems that this was done, but that the actual time taken in erecting these accumulators considerably exceeded the estimate. In consequence of this, the Chloride Electrical Storage Syndicate have claimed an additional £301 on a total of £1,147. It was urged on their behalf that the delay in building operations, etc., had caused this extra labour, while the case for the Corporation was that the tender of the company was for the complete battery of accumulators erected ready for working. Up to the time of going to press, Major Cardew's decision had not reached us.

COMPANIES' MEETINGS AND REPORTS.

ARON ELECTRICITY METER.

Yesterday, the third ordinary general meeting of this Company was held at Winchester House, E.C., Sir James Pender, Bart., in the chair.

The **Chairman**, in moving the adoption of the report, said they had had a most successful year, and had been able to show a good increase of business. The sales of the instruments had gone up for this year by 40 per cent. as compared with last year, and the profits, which in the prospectus showed a course of uninterrupted progress from £11,000 in 1892 to £18,000 in 1897, had now reached in the last two years £23,000 and £30,000 respectively. The increase in trade had been noticeable more particularly in England, though the profit in the United Kingdom this year did not show as favourably in proportion to the turnover as in the other countries. The reason for this was that they had arranged larger workshops, which would enable them in future to manufacture in England entirely, with the exception of the counting gears, which were manufactured for all their branches in their central factory in Schweidnitz. Now that the expenses of erection and organisation had been principally defrayed, they could look hopefully to a very much larger percentage of profit from the London business in the future. The orders for meters during the last two months since the end of their financial year—namely, October and November—exceeded in England by 40 per cent. the sales of the corresponding months of last year, and in the other branches an increase had also been made Every one of the branches had worked at a profit during the last year, the most satisfactory result being from the factory in Schweidnitz, which had shown this year a very handsome profit, and the directors had made arrangements for considerably increasing this factory, which should be the most remunerative department when the prices of raw material had again assumed a more normal aspect. The sale of the American patents was now so far effected that all but £4,000 in cash had been paid, and the stock to the face value of £33,000 had been handed to them and deposited with their bankers. Ample provision had been made for satisfying the best interests of the shareholders and the Company. Dr. Aron, during the past year, had succeeded in introducing further important improvements to suit the requirements of the station engineers, which consisted in the change over from wood to metal cases, in simplifying the design and manufacture of the meters, in the introduction of meters for special purposes, such as day and night load meters, hour meters, and automatic prepayment meters, and they looked forward to a considerable increase of business from these developments. Another distinct improvement had been the design of a small meter, which they called the "Cottage" type, now in the hands of the Board of Trade for official approval. This was a meter that could be made and sold at a considerably lower price, and could be used in small houses and shops in the poorer districts in town and country. They believed that this meter would meet completely the most stringent regulations of Government and municipal authorities, and be a large additional source of revenue in the future.

Mr. R. W. Wallace, Q.C., seconded the motion, and the report, together with the balance sheet, was adopted unanimously.

Mr. H. Hirst, a member of the Board, in reply to a shareholder, said they had never heard any rumours of legal proceedings in respect of their patents. Dr. Aron had a master patent dating back to 1883, and there was no ground whatever for such a suggestion.

In reply to another shareholder, Mr. Hirst said that with regard to the patents the Board of Trade were entirely on their side, and the County Council had no power to object to any patent which the Board of Trade had passed.

The following resolution was adopted unanimously: "That dividends at the rate of 6 per cent. per annum on the preference shares for the year ending Sept. 30, together with an additional ½ per cent. on the preference shares for the same period, and on the ordinary shares at the rate of 12 per cent. per annum for the year to Sept. 30, 1900, be paid, and that the payment of an interim dividend on the preference shares on April 1 last be confirmed.

The retiring directors, Messrs. R. E. B. Crompton and Mr. Hugo Hirst, were re-elected.

KALGOORLIE ELECTRIC POWER AND LIGHTING.

The ordinary general meeting of this Company was held on Wednesday at Winchester House, Mr. R. W. Wallace, Q.C., in the chair.

In moving the adoption of the report, which we published in last week's issue, the **Chairman** said he thought it was best that they should proceed slowly and be careful with regard to the expenditure of the funds of the Company. In consequence the Board had only spent money on such plant as could be kept in hand and dealt with on another site if they found it necessary to move from the site which they held. The shareholders must not expect that the undertaking would be remunerative in the first year or two of its existence, but there was every indication that in the course of a few years it would be earning large dividends, and the capital value of their shares would thereby be materially increased. He did not think that their Corporation ought to be mixed up in mining, and he was of the opinion that that property should be placed in the hands of a separate undertaking.

The report was adopted.

CAPE COPPER.

The thirteenth ordinary general meeting was held on Wednesday at the Cannon-street Hotel, Mr. Edmund A. Pontifex presiding.

The **Chairman**, in moving the adoption of the report, observed that the results of the Company's operations during the past year could not be considered otherwise than satisfactory. Their profits in the previous year were swollen by several adventitious aids. Another item in the accounts which had acted to the disadvantage of the present as compared with the previous year was that last year there was a sum of £22,685 which the directors were enabled to bring in to the credit of the year's operations from the Tilt Cove suspense account, which was now exhausted. Referring to the returns from the mines, he stated that the general result of the operations at Tilt Cove had been a profit available for division between the two companies of £59,299, as compared with £36,593

Digitized by Google

in the previous year. The mine at Nababeep would shortly form an important factor in their profit and loss account. The Bill which the Namaqua Company presented to the Cape Parliament asking for permission to construct a branch line from their mine to a point about 30 miles down the Company's line, and claiming running powers over this Company's railway, was eventually carried in the Lower House giving them all and more than they had asked in the first instance. Subsequently, however, the Upper House by a large majority threw out the objectionable clauses in the Bill—the clauses giving the Namaqua Company the running powers referred to. The directors had since been in friendly negotiation with the Namaqua Company, with a view to see if they could not come to such terms as to rates of carriage as would obviate the necessity of their making a branch line to join with the Cape Copper Company's; and he thought that they had practically succeeded in this endeavour though at a considerable loss of future revenue. They had made a satisfactory smelting arrangement with the Namaqua Company, and this should, in a measure, compensate for the loss incurred by the reduction in the rates of transport.

Mr. John Galsworthy seconded the motion, which was adopted.

MARCONI'S WIRELESS TELEGRAPH.

Directors: James Fitzgerald Bannatyne; Henry Jameson Davis; William Woodcock Goodbody; Guglielmo Marconi; John Mooney; Major Samuel Flood Page (managing director); Henry Spearman Saunder. Secretary: Henry W. Allen.

Report of the directors to be submitted to the fourth ordinary general meeting of the shareholders to be held at the offices of the Company, 18, Finch-lane, E.C., on Dec. 18, at 11 a.m.:

The period under review must be considered mainly as a further time of scientific and technical development, yet remunerative work has been carried out, the foundation of commercial business has been laid, and there is good promise of increased business in the immediate future; a profit and loss account is presented for the first time. The International Marine Communication Company was registered during the spring of this year, and has allotted 100,000 fully paid shares to this Company and 5,000 fully paid shares to its nominees. The International Company has commenced work. Their first installations have been erected on the Belgian coast at La Panne, and on one of the Belgian Government steamers. These have been quite successful and have attracted a great deal of public attention. The International Company has given orders for the erection of several stations on the coasts of the United Kingdom, and is engaged in negotiations with several Continental Governments. In August last, when the directors resolved to issue fresh capital, the offer of 25,000 shares at a premium of £2 was made to the shareholders, and an arrangement was made with a firm of brokers who undertook to take any number of shares up to 12,500 at £2 premium, for which the shareholders did not apply. Twelve thousand five hundred of the above shares have been subscribed and paid for by the shareholders and the brokers, subject to the brokers having a call on the remaining 12 500 at a premium of £2. 10s. per share. The transaction with the brokers was completed on Oct. 31, and £34 375 has been paid, of which only £1,076 comes into the present accounts. The chief business event has been the obtaining of a contract with the Admiralty for the supply and equipment of 32 sets of apparatus on payment of an annual royalty on each set. This is in addition to the five sets of apparatus which were transferred by the War Office to the naval authorities in South Africa. Only a small portion of the payment falls within the time embraced by these accounts; the benefit of this contract will be realised during the current year. The captain of H.M.S. "Vernon," under whom the work has been carried out, has expressed himself as satisfied therewith, and with the rapidity with which it was completed. Mr. Marconi has made great advances recently, some of which are of most undoubted value. We shall shortly be able to commence bringing them into use, and we may expect to derive much advantage therefrom. The works at Chelmsford have been improved and the plant and machinery increased, so that they can now turn out all the apparatus required, or likely to be required, during the next 12 months. The directors retiring by rotation are Mr. Guglielmo Marconi and Mr. John Mooney, who are eligible and offer themselves for re-election. The auditors Messrs Cooper Bros. and Co., also retire, and offer themselves for reappointment.

NERNST ELECTRIC LIGHT.

Directors: Sir Henry C. Mance, C.I.E. (chairman); J. G. Dalzell; B. Zusman; J. Geoffrey Fort; B. M. Drake, M.I.E.E. (managing director).

Report of the directors to be presented to the shareholders at the first annual general meeting to be held on Dec. 19, 1900, at the Westminster Palace Hotel, S.W., at 2.30 p.m.:

The directors beg to submit their report and balance-sheet, the latter embracing the period from Feb. 23, 1899, the date of the formation of the Company, up to Sept. 30 last. The expenditure on capital account during this period is shown to have been £9,695. 10s. 11d., while the disbursements on other accounts amount to £6,757. 6s. 11d. Acting on the advice of the auditors, the directors, after deducting from the latter amount £845. 14s. 4d. received on account of interest and transfer fees, have placed the balance of £5,911. 12s. 7d. to a development suspense account, to be dealt with in future years. Apart from the purchase consideration for the patent rights, the only prominent item of expenditure on capital account is a sum of £5,000 contributed towards the purchase for this Company of Prof. Nernst's British royalties, the balance of the consideration having been provided by the vendors. Intimation of this purchase was conveyed to the shareholders in a circular dated Dec. 9, 1899. As the owners of the British rights have not commenced business in England this investment is still unproductive, but as doubtless the Nernst lamp will shortly make its appearance in the English markets, it is anticipated that these royalties will constitute a considerable source of revenue. Since the formation of the Company the directors have been engaged in further developing the automatic Nernst lamp so as to render it more capable of being manufactured and sold in quantities on a profitable commercial scale, and with a uniform degree of quality and efficiency for the various sizes; they have also taken out subsidiary patents, which, it is hoped, will prove of considerable value. The fire which occurred on the Company's premises on May 31, 1900, and of which notice was sent to the shareholders, unfortunately destroyed the patterns, instruments, and apparatus collected with infinite care during the previous 12 months, and, notwithstanding the most strenuous efforts of the staff, progress was practically arrested for more than three months. As already reported, the Company was fully insured. While every discovery involving radical changes from existing methods must necessarily take time before the result can safely be placed on the market, your directors have found that the practical difficulties to be overcome in the wholesale reproduction of the Nernst lamp to the best advantage have been greater than they anticipated. The variations which occurred in endeavouring to repeat on a more extensive scale results already obtained have involved lengthy experiments and chemical research in directions where no precedent was available. It is now, however, confidently hoped that the main causes of such variations have been traced to their origin, and means devised for their elimination. The lamps at present prepared consist of 16 c.p., 32 c.p., and 50 c.p. for either 100 or 200 volt pressure; also a lamp of 150 c.p. for street and factory lighting. These lamps are made to light automatically in all sizes. The principal difficulty in connection with the lamp is the initial heating of the rod automatically. At present your directors are using wire-wound heaters, the best solution yet developed, but the Company have also obtained the exclusive rights for the Vogt resistance heater in all their territories, as well as in England. This heater, when perfected, may prove of great value to the Company. The 16 c.p. lamp is also made for lighting by means of a match or spirit flame. Although these recently-developed lamps are somewhat similar in appearance to those previously shown, they contain important modifications in their internal structure, the result of many months of study and invention. Your directors consider that the present lamps are sufficiently practical to warrant issue on a wholesale basis, and arrangements are now being made to push on with their production and sale. In this connection it should be considered that although all the licensees possessing rights for other parts of the world commenced work many months before the formation of this Company, and had, in most cases, the advantage of an organisation already equipped, this Company has, in the opinion of the directors, made at least as rapid progress in the practical development of the lamp as other concessionaires. The different patterns of lamps will be exhibited before the meeting. The retiring director is Sir Henry C. Mance, who offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., who have been auditors to this Company since its incorporation, retire, and being eligible, offer themselves for re election.

COPPER MINES OF MOUNT LYELL WEST.

The report of the directors of the Copper Mines of Mount Lyell West, Limited, for the year ended Aug. 31, to be presented at the meeting to be held in London on 18th inst., states that the expenditure in mining expenses was £5 189; auditors' fees, directors' fees, and secretarial expenses in London, less interest and transfer fees £1 044, being a total outlay for the year of £6,233. Mr. Currie, an expert, after making a careful examination of the Company's property, and having regard to discoveries in other not distant localities of valuable deposits attaining a high percentage of copper, recommended the continuing of the adit commenced by the manager and being driven from the old Razorback tunnel in a north-westerly direction so as to reach a point where certain strata contacts favourable to the deposit of copper may be expected, especially as in the vicinity surface works had disclosed favourable indications.

BOSTON CONSOLIDATED COPPER AND GOLD.

The report of the directors of the Boston Consolidated Copper and Gold Mining Company, Limited, to Sept. 30, to be presented at the meeting to be held in London on 20th inst., states that the amount expended by the American Company upon the development of the property, office and general expenses, etc., during the past year, less the amount realised from ore sales, etc., was 48,636dol. The management at the mines has deemed it wise to lease limited portions of ground to practical miners, who pay the Company a royalty on all ore extracted and assist materially in the exploration of the property. From this source the Company has received a net profit of 3,099dol. during the year.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Chinchilla.—The Municipality invite tenders for the electric lighting of the town for 20 years. Tenders by Dec. 20.

Asuncion (Paraguay).—The Municipality invite tenders for the installation of the electric light in the town. Tenders by Jan. 15, 1901.

Ploesto (Roumania).—The Municipality invite tenders for the installation and working of an electric tramway for 30 years. Tenders by Jan. 3, 1901.

Blackpool.—The Corporation invite tenders for the supply of arc lamp carbons and oils for one year. Tenders by Dec. 17. Details in our advertisement columns.

Aberdeen.—The Electric Lighting Committee invite tenders for the supply and erection of storage batteries. Tenders by Dec. 22. Details in our advertisement columns.

Leigh.—The Electricity and Tramways Committee invite tenders for the supply and erection of electricity mains. Tenders by Dec. 17. Details in our advertisement columns.

Madrid.—The Department for Agriculture, etc., invite tenders for the installation and working for 60 years of an electric tramway from Inrepets to Fogas and Boranova. Tenders by Jan. 7, 1901.

Hendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Swindon.—The Corporation invite tenders for three high-speed triple-expansion steam dynamos, one balancer, and one motor-generator. Tenders by Dec. 24. Details in our advertisement columns.

Harrogate.—The Corporation invite tenders for two high-pressure 30ft. by 8ft. 6in. Lancashire boilers, with fittings complete, and economiser. Tenders by Dec. 25. Details in our advertisement columns.

Bristol.—The Electrical Committee invite tenders for induced-draught plant, steam and electric feed and general service pumps, and water-softening plant. Tenders by Dec. 20. Details in our advertisement columns.

Battersea.—The Council invite tenders for the supply of ordinary and prepayment electricity meters, in accordance with specification No. 10. Tenders by Feb. 1, 1901. Details in our advertisement columns.

Swansea.—The Public Library Committee invite tenders for the electric wiring and fitting of public library, schools of science and art, and art gallery. Tenders by Dec. 17. Details in our advertisement columns.

Brighton.—The Council invite tenders for the supply of unarmoured and armoured lead-covered electric cables during the year ended Dec. 31, 1901. Tenders by Dec. 24. Details in our advertisement columns.

Partick.—The Corporation invite tenders for the construction, supply, and erection of steam dynamos, battery-charging motor, booster, and balancer. Tenders by Jan. 7. Details in our advertisement columns.

Ayr.—The Corporation invite tenders for the work required in forming permanent way, rail-laying, roadwork, etc, of about 5¾ miles of electric tramways. Tenders by Dec. 28. Details in our advertisement columns.

Middleton.—The Corporation invite tenders for superheaters, economisers, feed pumps and pipes, tanks, steam and exhaust pipes, valves, and accessories. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Leigh.—The Electricity and Tramways Committee invite tenders from manufacturers for the supply of 1,000 220-volt incandescent lamps during a period of 12 months. Tenders by Dec. 17. Details in our advertisement columns.

Ilford.—The School Board invite tenders for wiring and all ordinary fittings for about 200 lamps at 16 c.p., the Higher-Grade School, Melbourne-road, Ilford, Essex. Tenders by Dec. 17. Details in our advertisement columns.

Rathmines.—The Electric Lighting Committee invite tenders for the supply and erection of various plant for the extension of the municipal electricity works. Tenders by Jan. 10, 1901. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for the erection of an electric tramcar shed at Duckworth-lane, Manningham. Drawings, etc., may be seen at the office of the City Architect's Department, Chapel-lane. Tenders by Dec. 24.

Worthing.—The Corporation invite tenders for the supply and erection of a main switchboard. Specifications, etc., can be obtained from Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster, S.W. Tenders by Dec. 31.

Glasgow.—The Caledonian Railway Company invite tenders for telegraph and electrical appliances. Specifications, etc., may be obtained from Mr. J. Lorimer, stores superintendent, Charles-street, St. Rollox, Glasgow. Tenders by Dec. 17.

St. Pancras.—The Guardians of the Poor invite tenders for the installation of the Cook's-terrace Infirmary, Pancras-road, N.W., with electric light, according to drawings and specification. Tenders by Dec. 20. Details in our advertisement columns.

Leigh.—The Electricity and Tramways Committee invite tenders for the supply and delivery of the following motors and starting switches: one 10-h.p. motor, four 3-h.p. motors, three 2-h.p. motors, and three 1-h.p. motors. Tenders by Dec. 17. Details in our advertisement columns.

Tooting.—The Metropolitan Asylums Board invite tenders for the execution of certain wiring and other works in connection with the proposed electric light installation at the asylum now in course of erection at Tooting Bec. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of tramway bonds. Specifications, etc., may be obtained on application to Mr. J. M. M'Elroy, general manager, Tramways Department, Town Hall, Manchester. Tenders by Dec. 22. Details in our advertisement columns.

Thetford (Norfolk).—The Town Council invite tenders for supplying the wiring and fittings necessary for the electric lighting of the new town hall according to plan and specifications, which can be seen at the office of Mr. John Houchen, town clerk, London-road, Thetford. Tenders by Jan. 1, 1901.

Leeds.—The Lighting Committee invite tenders for electric lighting plant as follows: (Section A) two sets, each comprising engine of 2,000 b.h.p., two-phase alternator of 1,400 kw. capacity, and exciter; (B) two sets of surface-condensing plant. Specifications, etc., may be obtained from Mr. Harold Dickinson, manager of the department, 1, Whitehall-road, Leeds. Tenders by Dec. 31.

Manchester.—The Manchester Ship Canal Warehousing Company, Limited, invite tenders for the supply, delivery, and erection of 22 electric jib cranes required for work at the new transit shed, No. 8 dock, Manchester. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, M.I.C.E., chief engineer to the company, 41, Spring-gardens, Manchester. Tenders by Jan. 4.

Winwick (near Warrington, Lancs.).—The Committee of Visitors for the County Asylum invite tenders for (Contract No. 3) wiring, etc., including ring main and feeders, sub-main, lamp circuits, switchboards, distribution boards, fittings, etc. The drawings, etc. can be inspected at Winwick Hall, and also at the offices of the architects, Messrs. Crisp and Oatley and W. S. Skinner, Edinburgh-chambers, Baldwin-street, Bristol. Tenders by Dec. 29.

Werthing.—The Electric Lighting Committee invite offers from any person, firm, or company willing to instal, equip, and maintain a system of electric tramways in the borough, with power to the Corporation to acquire the same at any specific date upon agreed terms, such offers to specify the price to be paid for current to be supplied from the central station of the Corporation electric lighting works. Tenders by Dec. 31. Details in our advertisement columns.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

Wolverhampton.—The Tramways Committee invite tenders for the supply of the necessary materials and labour for the construction of tramway track and contingent works in Tettenhall-road, New Hampton-road, Waterloo-road, Darlington-street, Queen-square, Lichfield-street, Fiveways, Piper's-row, Bilston-street, Cleveland-road, and Bilston-road to the borough boundary, amounting to a route length of about 4½ miles, mainly double track. General conditions, etc., may be seen at the office of Mr. J. W. Bradley, M.I.M.E., borough engineer and surveyor, Town Hall, Wolverhampton. Tenders by Jan. 15.

RESULTS OF TENDERS.

Colne.—The tender of Messrs. Parsons, Newcastle-on-Tyne, at £1,161, has been accepted for a steam-turbine and dynamo.

Swansea.—The contract of Mr. Hy. Coles, Swansea, at £326, for wiring and fitting of installation in the station, has been accepted.

West Bromwich.—The tender of the Alliance Electrical Company, Birmingham, has been accepted for the supply of motors and switch gear for hiring.

Brighton.—The tender of Askham Bros. and Wilson, Limited, of Sheffield, at £3,627, for the supply of points, sole-plates, manhole covers, tie-bars, etc., has been accepted.

Salford.—The Town Council have accepted the tender of the Oldham Boiler Company, Limited, for the supply of the steam and blow-off pipes for the additional plant for the sum of £65.

Digitized by Google

Lowestoft.—The Town Council have accepted the following tenders for the extension of the generating plant: (Section A) Babcock and Wilcox, two boilers £1,519, brickwork £180 (completion within 16 weeks of signing contract); (B) Babcock and Wilcox, pipework, £419 (completion within 10 weeks of signing contract); (C) Lancashire Dynamo and Motor Company, 250 kw. dynamo in connection with the Browett and Lindley engine, £2,200 (completion within 25 weeks of signing contract)

Maidstone.—The Corporation have received the following tenders for surface condenser:

Wheeler Condenser Company, Limited	£1 010 0 0
British Power, Traction, and Lighting Company, Limited	1,164 0 0
Cole, Marchent, and Morley, Limited (accepted)	1,209 10 0
Allen, Sons, and Co., Limited	1 307 0 0
Edwards and Barnes	1 398 0 0
Davey, Paxman, and Co., Limited	1 596 0 0

Southwark.—The Electric Light Committee have received the following tenders for supply and erection of certain back E.M.F. cells at the Corporation electric light station, Penrose street, Walworth-road:

Tudor Accumulator Company, Limited	£588
Hart Accumulator Company, Limited	565
Electric Power Storage Company, Limited	509
British Power, Traction, and Lighting Company, Hull-road Works, York	390
Pritchetts and Gold	349

Cardiff.—The Tramway Committee have received the following tenders for plant:

BUSINESS NOTES.

LIGHTING AND GENERAL.

Beverley.—The draft electric lighting provisional order has been adopted.

Leyton.—Extensions of mains, estimated to cost £200, have been authorised.

Barrow.—A coal conveyor is to be erected at the electricity work, at a cost of £70.

Stockton.—The opening of the electric light works will take place within a few days.

Leigh.—The Town Council propose to apply for a loan of £500 for the purchase of electric motors.

Wearmouth.—The question of lighting the Wearmouth Bridge with electricity is under consideration.

Leith.—Mr. George W. Grosset, of Edinburgh, has been appointed junior assistant for generation.

Partnership.—We beg to refer to an advertisement which appears under this heading in another column.

Glasgow.—We are pleased to note that the Town Council have raised Mr. Chamen's salary to £1,000 per annum.

Boston.—The Town Council propose to obtain an expert's opinion on private and public lighting in the town.

Ilfracombe.—It is proposed that the Council transfer their electric lighting provisional order to a private company.

Gosforth.—The Urban District Council have decided to oppose the proposed North Shields and Gosforth tramways scheme.

St. Annes.—The Urban District Council have obtained a loan of £18,000 for private street work, electric lighting works, etc.

Kingston.—The Guardians have adopted a report adverse to the installation of a plant to generate their own electric light.

Sevenoaks.—Mr. W. M. Mordey has been appointed by the Urban District Council to act as consulting electrical engineer.

Walmer.—The District Council have appointed a committee with power to consult an expert on electric lighting and tramways.

Bury.—Application is to be made for a loan of £6,000 for the purposes of public lighting, including the roads on the Brown Estate.

Barnstaple.—A report has been obtained showing that an adequate electric lighting scheme for Barnstaple would cost £14,000.

Aldershot.—The report of the Electric Light Committee will be presented for consideration at the December bi-monthly meeting.

Cork.—The Sunday's Well extension branch of the Cork electric tramways system has just been opened, and trams will run regularly.

Sale.—The Urban District Council have decided to engage Mr. Charles Hopkinson to prepare plans, estimates, etc., for an electric lighting scheme.

Lymington.—The electric lighting was started at the works last week, and the supply will be available for private consumers almost immediately.

East Ham.—A Local Government Board enquiry was held on Wednesday into the application of the Council to borrow £42,220 for electric tramways.

Sheffield.—The Electric Light Committee are recommending several increases in the salaries of their staff, amounting altogether to £117. 8s. per annum.

Middlesbrough.—We learn that the laying of the electric mains is now practically complete, and that applications for the use of the light are coming in steadily.

Fulham.—The Borough Council have agreed that application be made to the Board of Trade for their sanction to supply the light to the Guardians at a reduced rate.

Leamington.—A deadlock has arisen between the Leamington Corporation and the British Electric Traction Company with regard to the interpretation of the agreement.

Surbiton.—A portion of the ratepayers appear to be much incensed against the coming tramways, but we are informed that the vote will go in favour of their introduction.

Buxton.—The engineer's estimate of the cost of laying a cable to Haddon-grove—625 yards—is £242. Additions equivalent to 300 8-c.p. lamps have been made during the month.

Hammersmith.—Application is to be made to the London County Council for their sanction to the borrowing of £15,000, being the cost of extending the electric mains in the borough.

Wimbledon.—The Urban District Council on Wednesday decided not to proceed with its Improvements Bill, which included the proposed tramway from Tooting to Wimbledon Station.

Rotherham.—The Rural District Council are enquiring into the Yorkshire Electrical Power Syndicate's circular propounding a scheme for supplying electric power in the West Riding of Yorkshire.

Dalkeith.—Messrs. Crompton and Co., Limited, propose to supply the burgh at 3d. per unit and to fix up and maintain all the necessary lamps, etc. Mr. A. Campbell Swinton is being consulted on the matter.

East Barnet.—The North Metropolitan Electrical Power Distribution Company have abandoned further action in the application for a provisional order in the coming session with regard to the Urban District Council's district.

Newport.—Mr. E. Cardin has been appointed mains superintendent at £150 per annum, in succession to Mr. Howard. An agreement will be entered into with Mr. Parshall for carrying out the electric tramways and power station.

Birkenhead.—The Electricity Committee have appointed a sub-committee, consisting of the chairman, the deputy-chairman, and Messrs. Dodds, Hazlehurst, and Moon, to report and eventually recommend a scheme for assisted wiring.

Kirkcaldy.—The Town Council have decided that Links-street, from the West-end to the cottage hospital on the tramway route, also the thoroughfares leading to the railway station, be lighted with electricity, at an estimated cost of £14,000.

Great Harwood.—A letter from Messrs. Tabourdin and Hitchcock, asking the Council to pass a resolution in favour of electric lighting for Great Harwood, and submitting plans, etc., is before the Highway Committee of the Urban District Council.

Darwen.—Messrs. D. Bruce Peebles and Co., of Edinburgh, have received an order from the Darwen Corporation for a 600-h.p. traction generator. The machine will be direct coupled to a high-speed vertical engine of Messrs. Belliss and Morcom's make.

Digitized by Google

Audenshaw.—The District Council have served a notice upon the Manchester Carriage and Tramways Company respecting the purchase of the company's undertaking in the Council's district.

Islington.—The Provisional Electric Lighting Committee are about to report upon the machinery, plant, mains, and running of the electric lighting undertaking of the Council. They will, if necessary, employ a consulting electrical expert for the purpose.

Bristol.—The puzzle, "Engineer or Architect," in connection with the foundations of the generating station is still engaging the attention of the Corporation. By last advices we learn that the report recommending to do without an architect has been rejected.

Brompton and Kensington Electricity Supply Co.—The transfer register of the 4½ per cent. mortgage debenture stock of this Company will be closed from the 21st to the 31st inst., both days inclusive, for the preparation of warrants payable on Jan. 1.

Tunbridge Wells.—Arrangements have been made for the provision of a switch-room at Tunbridge. The Town Council have resolved that the telephone cables in the borough be laid in the roadways as much as possible, and that an instrument fitter be engaged.

Stock Exchange.—Electric shares were in favour on Monday, but quotations did not move enough to call for comment. Tractions were easier. For the rest of the week electrics were almost without feature, and only a trifling business was doing in them.

Burgess Hill.—At a recent meeting of ratepayers it was agreed to urge the Urban District Council to continue the application for an electric lighting provisional order, and, when obtained, the ratepayers, in public meeting assembled, be consulted as to the best way to deal with such order.

Wigan.—From what transpired at the last meeting of the Borough Council we gather that the Electric Light Committee are now within measurable distance of being able to supply electric current not only to all those who have fitted up ready for it, but to all those who are desirous of having it.

Electric Governors.—We are informed by Mr. E. Thunderbolt that the electrical marine governors designed by him, and illustrated in one of our recent volumes, are meeting with a good reception commercially. The Allan line have recently ordered five more of the marine type of governor.

East Molesey.—Edmundson's Electricity Corporation have informed the Council that they have abandoned their intention of applying for a provisional order, and that they would be prepared to offer the Council a supply of current in bulk when the Council were in a position to carry out their order.

Kingston.—A committee of ratepayers has been formed to support the Corporation tramways proposals, and every effort will be made before the date of the polling to bring home to the burgesses the intentions of the Corporation in regard to the promotion of a Bill in Parliament for powers to construct tramways in the borough.

Clayton-le-Moors.—A plan and notice for the electric light order to be submitted to the Board of Trade by Mr. W. C. Chadwell, of Richmond-chambers, Blackburn, has been referred to a Light Railway Bill Committee of the Urban District Council. The Council have decided to co-operate with the Great Harwood Council in this matter.

Littlehampton.—The North British Electric Supply Company, of South Shields, have informed the Urban District Council of their inability to proceed this session with their intended application for a provisional order to supply Littlehampton with electric light. However, they hoped to do so the following session, before which they would seek an interview with the Council.

Stafford.—During last year the consumption of gas increased by 4 per cent., while that of the consumption of electricity increased by 160 per cent. The laying of a twin arc cable as far as the Baptist Church in Lichfield-road, at a cost of £162. 10s., will now be undertaken. The salary of Mr. J. H. Clothier, assistant electrical engineer, has been increased by £25 per annum.

Pocklington.—At the last meeting of the Urban District Council a report was submitted by a deputation of their recent visit to the Northallerton electrical works, in which they state that they see no reason why a similar scheme should not be worked successfully at Pocklington, the only question being whether a plant could be installed on a paying basis. A town's meeting is to be called to discuss the question.

Edinburgh.—The Cleaning and Lighting Committee have agreed to obtain an estimate of the cost for lighting various streets with electricity by lamps suspended in the middle of the street. Mr. Cameron considers that in narrow thoroughfares this system would be much cheaper and more efficient than ordinary lamp-posts, while in addition the suspended lights would leave the already narrow pavements clear of any obstruction.

Rochdale.—The following will be the scale of charges for current after Jan. 1 next: (1) for the supply of electricity for lighting on the maximum demand indicator system, 6d. per unit for 100 hours' consumption of the maximum demand per quarter, and 4d. per unit for all units in excess of this quantity, the maximum demand indicators being supplied and maintained by the Corporation without charge; (2) the price per unit for purposes other than lighting to remain at 3d.

Personal.—Mr. A. Heilbron has been appointed manager of the special department for cables, wires, and insulating material recently established by the Electrical Company, Limited, Charing Cross-road.—We are pleased to note that Mr. A. Hugh Seabrook, A.M.I.Mech.E., A.M.I.E.E., assistant engineer at the borough electricity works, Hampstead, has been appointed resident engineer to the Barking electricity works. We learn that Mr. Seabrook relinquishes his present post in one month's time.

Yeadon.—The Board of Trade have notified the District Council that they are of opinion that the Council's electric lighting order should not be allowed to remain in force any longer, and the Board therefore propose to revoke the order forthwith. In consequence of a circular issued by the Yorkshire Electric Power Syndicate, Limited, the various urban and rural councils in the Wharfedale Union are to be invited to attend a joint meeting for the purpose of deciding if any joint action should be taken.

Swansea.—Applications for 5,115 8-c.p. lights have been received, and the Council have decided to extend the mains through College-street and Heathfield-street, but to postpone other streets till at least three applications from private consumers had been obtained in each. The Grand Theatre will be supplied at 3½d. per unit, the standing scale being departed from in this as with regard to the Harbour Trust. A conference is taking place between the Council and representatives of a free wiring company.

London Gazette.—The discharge of W. J. S. Green, 45, Birchfield-road, Aston, Warwick, has been suspended for two years. The estates of B. Wild and J. H. Clarke, trading as Wild, Rothwell, and Co., Atlas Works, 62, Virginia-street, Southport, have been released from trusteeship. The last day for receiving claims in the matter of the Nuneaton Electric Company, Limited, has been fixed for Feb. 1, 1901. A belated advertisement appears in the last *Gazette* by the Southport Corporation for a tramways provisional order.

Aberdeen.—The drawings, etc., for the Girdleness outfall sewer and the subway in Crown-street for the electric lighting department have been completed. The actual cost falling on the electrical department is estimated at £8,400, in place of £6,600, as originally estimated, of which sum about £1,500 represents the extra expense in strengthening and altering the sewer. The Council have decided to procure a destructor capable of burning from 12 to 13 tons of refuse per working day of 10 hours. The cost is estimated at £750.

Stirling.—The Police Commissioners of Stirling have resolved to erect an additional 30 arc lamps, the estimated cost being £915 and the annual charge £435, equal to 1½d. extra on the rates. The lighting station is also to be extended by the addition of other two Lancashire boilers, two dynamos, feed pump and heater, and other plant at a cost of about £10,000. The Police Commissioners are endeavouring to come to an agreement with the British Electric Traction Company and the Bridge of Allan Tramways Company for the disposal to them of their rights.

Ayr.—A sub-committee has been appointed to consider the proposed application to the Board of Trade for permission to change the system of supply from the present voltage to a voltage of 250. It has been agreed to grant the supply to the Auction Company at 5d. per unit, plus 5 per cent. on £10, being the estimated cost of the cable extension chargeable to the company, the minimum charge to be £1 per annum; and the following terms will be offered to the G. and S.-W. Railway Company: for 100,000 units, 2½d. per unit; up to 200,000 units, 2d. per unit; up to 300,000 units, 1½d. per unit.

East Ham.—The Council have adopted a report upon the question of supplying electric light to the artisans' dwellings, showing that the capital outlay for wiring and fitting these houses is £6. 10s. per double-tenement house, to which has to be added the sum of 2s. per house covering loan charges. High-street South and the Manor Way to the Ferndale Tavern, North Woolwich, is to be lighted with arc lamps placed at a distance of 80 yards apart. The portion of the Highway to Beckton-road will be proceeded with forthwith, and the remainder at the time the tramway track is being constructed.

Appointments Vacant.—It has been decided to advertise for a general manager of the tramways about to be taken over by the Burnley Corporation, at a salary of £350, rising to £400 at the end of three years.—The Bexhill Urban District Council require the services of a shift engineer.—At the Plymouth Corporation and at the West Hartlepool electricity works there are vacancies for switchboard attendants.—The Edinburgh Corporation require, at once, an inspector to superintend the installation of electric lighting at a large public building.—The Borough Council of Bermondsey invite applications for the position of mains foreman.—The Wimbledon Urban District Council require, at once, a junior assistant engineer at their electric light station, Wimbledon. Full particulars of these vacancies appear in our advertisement columns.

London County Council.—The Council have granted notices under Electric Lighting Acts and orders from the Blackheath and Greenwich District Electric Light Company, under the Blackheath and Greenwich District Order, 1897, of intention to lay low-tension mains along a portion of London street, Greenwich; and from the County of London and Brush Provincial Electric Lighting Company, under the Wandsworth Order, 1892, of intention to lay low-tension mains along both sides of and across Putney Bridge-road. Also plans by Mr. W. B. Pinhey on behalf of the Charing Cross and Strand Electricity Supply Corporation Limited, for the construction of a building, to be used as a sub-station and offices, on the site of 59, 60, and 61, St. Martin's-lane, Strand. They refused to approve of the plans submitted with the application of Messrs. Church, Quick, and Whincop, on behalf of the Woolwich District Electric Light Company, Limited, for the construction of an addition to an electric light station at the company's works, Globe-lane, High-street, Woolwich.

Digitized by Google

Kingsbridge.—At the meeting of the Urban District Council last week letters from Mr. Mildmay, M.P., and the Postmaster-General were read relative to providing telephone communication. It was stated that the National Telephone Company could not continue the work begun, as too much time had elapsed before connecting with the exchange, and if 15 subscribers of £3 each were obtained the Post Office would provide it. It was resolved to let the matter stand over for a time, as probably the Post Office authorities would take it up.

Goole.—At the last meeting of the Rural District Council a circular was read from the Yorkshire Electric Power Syndicate, notifying the Council that they were about to apply in Parliament for power to launch a large electric lighting scheme for the West Riding, the area of which comprised 158 local authorities. The circular stated that the syndicate was formed by Yorkshire manufacturers and colliery owners, and they intended the syndicate to provide electricity to local authorities and not for general distribution. Nothing was done in the matter.

Presentations.—On Friday, Dec. 7, at Falcon Works, Loughborough, Mr. E. W. Jones was presented with a high-class planimeter by the members of the Brush Company's staff on his leaving to take up the position of leading draughtsman to Messrs. Reavell and Co., of Ipswich.—Sir Edward Gourley, on behalf of the Sunderland Tramway Company, last week presented Mr. William Morrison, late manager under that company, and now traffic of the Corporation tramways, with a gold watch and gold curb chain, while Mrs. Morrison was the recipient of a gold watch bracelet.

Aylesbury.—The Urban District Council will at their next meeting further discuss a report which they have received from Councillor Reader, chairman of the Lighting and Fire Brigade Committee. The report shows that the committee, after consultation with Mr. Medhurst, have come to the conclusion that with a capital expenditure of £23 211 the public lighting of the district and about 4 000 8-c.p. lamps for private supply could be maintained and that the revenue from 3,000 lamps would be sufficient to pay expenses, leaving the revenue from 1,000 lamps, on which a profit would be shown at once.

Nelson.—The Local Government Board have just sanctioned the borrowing of £2,500 for purposes of electric lighting. The date of repayment has been fixed at seven years, and the Council are protesting against the shortness of the term. An expert engineer is to be consulted on the subject of the proposed alterations and additions to the electrical works of the Corporation. The electrical engineer's report for the past month shows that the quantity of electrical current sent out during the month was equal to 12,818 units, an increase of 18 per cent. over the quantity sent out for the corresponding month last year.

Ferranti, Limited.—We have been asked to review a little pamphlet descriptive of this company's works at Hollinwood, Lancs., and of the standard manufactures emanating therefrom, and we do so with pleasure, not exactly because the booklet is a reprint from the *Electrical Engineer* of May, 1900, but also on the perhaps more justifiable ground that it is really an excellent production, giving a large number of fine illustrations well executed on hyperfine art paper. We are informed that Messrs. S. Z. de Ferranti Limited, will be pleased to send a copy of this pamphlet (No. 113) to any of our readers interested in the same.

Hackney.—A piece of land at Millfields-road, adjoining the River Lea, has been purchased of St. Thomas's Hospital authorities for the sum of £8,000, as a site for electric lighting station, refuse destructor, also disinfecting station, etc. The estimated capital expenditure in respect of the electric lighting of the borough amounts to £242 367, of which £80,000 has already been borrowed of the London County Council, and the committee last night asked for the authority of the Borough Council to borrow the balance—namely, £162,367—at such times and in such amounts as they may be advised by the Electric Lighting Committee.

Consett.—The Electric Lighting Committee of the Urban District Council have considered notices from the Northern Counties Electricity Supply Company and the Cleveland and Durham Electric Power Company as to a provisional order under the Electric Light Acts of 1882, 1888, and 1889 by the first company, and a Bill by the other company. They desire to be empowered to deal with the provisional order and the Bill, and to employ any assistance they might require. The Council have given conditional consent to the Northern Company to come into the district providing they carried out an agreement which has not yet been signed. The matter will come before a special meeting shortly.

York.—Mr. R. H. Bicknell has held an enquiry into an application of the City Council for sanction to borrow £20,000 for electric lighting extensions. It was stated that so far the electric light had been a great success in York. The original scheme, as was explained by the town clerk (Mr. W. H. Andrews) and the electrical engineer (Mr. C. A. Midgley), provided for plant for the supply of 6 000 lamps each of 8 c.p. The supply was commenced on April 1 last, and there are now applications for light equivalent to 18,000 lamps. To meet this exceptional call extra plant is required for the present winter, and also in preparation of the still greater requirements of next winter. Extensions of mains have been carried out by Prof. Kennedy at a cost of £1,475, and the demand has amply justified the outlay.

St. Marylebone.—The Guardians have adopted a report of the Infirmary Visiting Committee, recommending "That in answer to a letter received from the Local Government Board, they be asked to receive a deputation from the Guardians of this parish on the correspondence that has taken place between this Board and the Local Government Board on a proposal of the Guardians to generate their own electric current for the electric lighting of the infirmary, the committee feeling that a personal interview between the Local Government Board and the deputation may remove any doubt existing in the minds of that Board as to the saving to the parish which will be effected by generating the current in the institution." The Local Government Board had written that, having regard to all the circumstances, they were of opinion that the Guardians would be well advised to allow the matter to stand over until next year, and that the wiring, etc., of the building should alone be undertaken in the early spring in anticipation of the supply of current by the Notting Hill Electric Lighting Company in April at 4d. per unit.

A Useful Pocket Book.—We have received from the Scientific Publishing Company, Manchester, a copy of "Fowler's Mechanical Engineer's Pocket Book for 1901." In the preface we are told advantage has been taken in the new issue of the opportunity to thoroughly overhaul the contents of the book, so as to bring it up to date and eliminate any little errors that previously existed. An immense amount of useful information relating to apparatus, etc., with which mechanical and electrical engineers have to deal is condensed into its pages. Tables of equivalent weight and measures, so useful for reference, besides much valuable data in the shape of formulæ etc., are included. The section devoted to traction work should render the little annual especially useful just now, when this branch of the electrical industry is so busy. Appended are some memoranda sheets and diagram forms for graphic records—another useful feature. The book is, however, already too well known to call for further review of its comprehensive contents here. Suffice it, in conclusion, to add that as a reliable and convenient work of reference its popularity is fully deserved.

Brighton.—Colonel A. G. Durnford has held an enquiry into the application of the Town Council to borrow £56 500 for purposes of electric lighting. The Town Clerk (Mr. F. J. Tillstone) said the money was required for the expenses in respect of the electricity undertaking for the years 1901 and 1902, and it was proposed to extend the repayments over a period of 25 years. Mr. Christie, the electrical engineer, stated that the present capacity of the works was 4 710 kw., equivalent to 147,000 8-c.p. lamps, and at present they had 150,000 lamps connected. They had a prospect of also lighting the new pier that was being built, and the local tramways would be run with power from the works. The pier would probably require an additional 2,500 and the tramways 11,000. New consumers were coming on to the mains at the rate of from 400 to 500 per annum, and the increase of business might be taken at about 16 per cent. on the previous year's output, both as regards output of energy and connections for new consumers. He stated that the tenders for the proposed plant which had been accepted had proved somewhat below the estimate, and therefore the Corporation would only require some £54 798.

Cardiff.—The appointment of Mr. Ellis, notified by us last week, was ratified by the City Council on Monday. We purloin the following biographical note from the *Western Mail*: "Mr. Arthur Ellis, who was on Monday appointed by the Cardiff Corporation to the position of chief electrical engineer for lighting and traction, is a son of Alderman J. Baxter Ellis, J.P., an ex-mayor and ex-sheriff of Newcastle-on-Tyne. He was educated by a private tutor at St. Bees Grammar School, Cumberland, and served his time as a premium apprentice to Messrs. C. A. Parsons and Co., Newcastle. His first appointment was as assistant engineer to the Newcastle and District Electric Supply Company. He gave this up in order to become chief engineer of the Cambridge Electric Supply Company, with whom he remained for two years. In April, 1894, Mr. Ellis was appointed borough electrical engineer at Southport, where he laid down a large station for lighting purposes. Two years later he obtained a similar but more lucrative position at Bolton, where he extended the system very considerably. In 1897 he changed the system from alternating to continuous current, and at the same time laid down a large tramway installation over 25 miles of streets. In 1899 he was appointed general manager to the electric tramways and lighting departments of the Bolton Corporation, in which capacity he had between 300 and 400 men under his charge, and paid in wages over £400 a week. He obtained the position of electric tramways engineer at Cardiff in June last, and entered upon his duties on Sept. 1 at a salary of £500, notwithstanding that the Bolton Corporation offered him a substantial increase to remain in their employ. As chief electrical engineer for Cardiff he now receives £750, rising by annual increments to £1,000."

TRACTION.

Bristol.—The work of altering the tramlines in the west of the city was begun on the 10th inst.

Stockport.—We learn that the electric tramway system will probably be in working order by May next.

Rochdale.—The appointment of Mr. Platt as the engineer for laying the permanent way of the electric tramways has been confirmed.

St. Helens.—Trial runs are taking place on the extension of the St. Helens tramways from Ramhill to Prescot and down to the Royal Hotel.

Nelson.—Negotiations are still proceeding between the Burnley and District Tramways Company and the various local authorities as to the sale and purchase of the tramway undertaking.

Digitized by Google

East Molesey.—The Council have decided to oppose the London United Tramways Company's application for powers to construct further tramways running partly through this district.

Personal.—Mr. E. J. Marsh has been appointed chief electrical superintendent of the tramways department of Sheffield Corporation at a salary of £150 per annum, increasing annually by £10 up to £200.

Glasgow.—The Tramways Committee have postponed discussion on the proposed reduction of fares until a report has been received from the general manager on the working of the electric traction system now being installed throughout the city.

West Bromwich.—The Town Council have appointed a committee to enter into negotiations with the South Staffordshire Tramways Company, Limited, and the Birmingham and Midland Tramways Company, Limited, for the immediate purchase of their lines.

Northfleet.—The National Electric Traction Company, Limited, have now completed their arrangements for carrying out the works under the Gravesend, Rosherville, and Northfleet tramways order. The work will be commenced early in 1901. A local company will be formed.

Hampstead.—The deposited plans and sections of the Charing Cross and Hampstead Extension Railway have been referred to Mr. A. P. Johnson, town clerk, and Mr. C. H. Lowe, surveyor, for consideration and report. The scheme is meeting with strong opposition on account of the proposal to carry the railway under a portion of Hampstead Heath.

Worcestershire.—The County Council have agreed to contribute £1,900 towards £3,138, the ascertained cost of widening the canal bridge at Selly Oak, which will allow a double line of tramrails over it. The King's Norton and Northfield District Council agree to contribute £500, and the City of Birmingham Tramways Company provide the remaining sum.

Airdrie.—The Town Council have asked Prof. Kennedy to do what he considered necessary to place the Scottish House-to-House Electricity Company, Limited, under a binding obligation to construct the tramway from Motherwell-street to Clarkson Church within six years from the passing—July 30, 1900—of the Airdrie and Coatbridge Tramways Act, 1900.

Manchester.—A special meeting of the City Council will be held on Jan. 9 to consider and decide whether the Council shall require the tramways company to sell to the Corporation so much of the undertaking authorised by the Manchester Suburban Tramways Act, 1879, as the Corporation are entitled to purchase, and to adopt a resolution to require the sale if so decided.

Preparing for Winter.—At the last meeting of the Sunderland Health Committee the question of clearing the tramway routes when a fall of snow occurs came up for discussion, and it was agreed that the committee should do the work. When snow falls a car will be kept patrolling the lines to clear them as much as possible, and the Health Committee will sweep the lines clear and remove the snow.

New Malden.—The result of the recent post-card poll showed a majority of 190 in favour of tramways. The Council have agreed not to oppose the London United Company in their application for powers to construct the tramway, but they have reserved to themselves the right to negotiate as to clauses, provided the company, under their common seal, would withdraw that part of their scheme which related to the ward of Coombe.

Standish.—At a recent meeting of the Highways Committee a deputation from the Wigan Corporation waited upon the committee for the purpose of discussing the conditions of Standish Council relative to the proposal by the Corporation to construct and work electric tramways within the district of Standish-with-Langtree. A number of conditions were discussed, and eventually an agreement was come to with reference to the widening of the road and Boar's Head Bridge, fares, etc.

Hull.—The first car was run along the Beverley-road to Newland on Saturday. Alderman Larard, the chairman of the Works Committee, drove the first car, which was crowded with members and officials of the Corporation. Upon the return journey there was a capital amateur conductor on board—viz., Councillor Latus—who insisted upon collecting fares from everybody in the car, and, after doubling the amount received out of his own purse, handed over the proceeds to the Mayor's war fund.

Birkenhead.—The Tramways Committee have made arrangements to allow the Birkenhead United Tramways, Omnibus, and Carriage Company, Limited, to continue to use the existing lines after the expiration of their lease at the end of this year, and the new lines when constructed at the nominal rent of £3 a month, the arrangement to be terminable by four weeks' notice by either party, and the Corporation reserving the right to reconstruct, construct, and equip the tramways as whenever and wherever the borough surveyor may decide.

Plea for First-Class Carriages.—In reference to the new electric railway from the Bank to Shepherd's Bush, on which there is no distinction of class in the carriages, "S" writes to the *Morning Post* that the "democratic principle" is sometimes not altogether satisfactory. He does not say anything against working-men passengers, whose clothes must of necessity be suited to their work, but he points out that their raiment is sometimes such as to make it desirable on the part of those not engaged in industrial occupations to take a higher class of conveyance if that were available. "It is," he adds, "not so much for different classes of society that separate class railway carriages are needed, but that they do appear desirable for certain classes of clothes, and it is a privilege for which many well-dressed men and women would be willing to pay an increased fare." There is a good deal in this contention, especially as the people alluded to do already pay a higher fare.

Reading.—At the last meeting of the Town Council the Town Clerk reported that the Reading Tramways Company, Limited, had not accepted the offer made to them of the sum of £10,105 for the purchase of their undertaking, but that their soliciter had written to say that until a final decision had been arrived at in the proceedings now pending between the company and the Corporation, it was impossible for the directors to entertain any offer for purchase of the tramway undertaking for the sufficient reason that, in the event of the decision being in their clients' favour, the Corporation would have no power to acquire the tramways on any terms whatever. If, under these circumstances, the Corporation should proceed with their intention to apply to the Board of Trade to appoint a referee, the company would resist any such appointment. An application is to be made to the Board of Trade to appoint a referee pursuant to Section 43 of the Tramways Act 1870. It was further resolved to recommend to the Council that the borough engineer and Mr. J. E. Winslow be directed to proceed forthwith with plans and specifications of the works and machinery required for the station for generating electrical power, and to submit the same to the committee as early as possible.

Dundee.—The electric cars commenced running on the Perth-road on July 13. The passengers carried in July numbered 519,846, being an increase of 59,900 on the corresponding month of last year, and representing receipts enhanced to the extent of £221. 8s. 11½d. On October 22 work was commenced on the Lochee section. The total increase for the last six months compared with the same period last year is £1,380. 11s., while the advance in the number of passengers is 405,268. Since the introduction of the electric cars it is satisfactory to record that there has been entire immunity from accident. We learn from the *Dundee Advertiser* that "at a recent meeting of the Tramway Committee Mr. Fisher, the manager, reported that he had designed a new car, which in his opinion would fulfil all the requirements entailed by the conditions of traffic applicable to the Constitution-road tramway. The new type of car differs materially from any of those at present belonging to the Corporation. In the first place, it is larger, being 36ft. in length, which is 6ft. longer than the cars running on the Lochee section. Externally it is of elegant appearance. It is of the single-deck type—that is to say, no provision is made for carrying passengers on the top, which in construction is framed pretty much on the lines of American cars, ensuring thorough ventilation of the interior. The car is divided into three compartments. The end compartments are each seated for 10 persons, while in the middle compartment there is accommodation suitable for 24 passengers. The end compartments are fitted with movable windows, so that this part of the vehicle may be used as a semi-open carriage. By this division special accommodation may be accorded to smokers, while it also permits of a classification according to fare. At each end is a platform 2ft. 6in. long for the motorman and conductor. The new car is specially adapted for hill-climbing. The body rests on what are technically called '27 J. Brill trucks.' The propelling power is furnished by four motors, each coupled to an axle. To ensure safety of descent, the car, in addition to the ordinary and emergency brakes, is fitted with what is known as a slipper brake. By this piece of mechanism the brake proper is made to operate on the rail. The speed of the car when descending a steep gradient is thus retarded, and can be regulated to a nicety by the application of the ordinary working brake. Plans and a description of the new hill-climbing car will be submitted to the Tramway Committee on an early date."

Sheffield.—The Brightside section was only "passed" by the Board of Trade on the 6th, and 18 cars commenced running on the Tinsley section on Saturday last. At the next meeting of the City Council it will be proposed that the resolution of the Tramways Committee to lay a tramway from the bottom of Hounsfield-road along Glossop-road, Clarkehouse road, and Brocco Bank, to connect with the Ecclesall-road tramway, be not for the present proceeded with, nor until further instructions are given by the City Council after full consideration as to the advisability or necessity for such tramway. We have received a copy of Mr. Chas. F. Wike's (the city surveyor) report for the year ending March 31, 1900. Of course the electric tramways are only a portion of the vast amount of work which comes under the surveyor's department in the important town of Sheffield, and, in consequence, only a portion of the report deals with the tramway construction work. It is shown, however, that the tramways during the year were responsible for an outlay of somewhere about £50,000 by the surveyor's department. This was chiefly spent in reconstruction of the tracks for the heavier electric cars, and in the provision of the trenches and conduits for the electric conductors. In the report for the tramway department full details of the various lines which have been made during the year are given, together with information as to the way in which the tramway tracks have been paved. We gather from this section that two systems have been employed for the paving, the one being wood blocks and the other the tar macadam with granite setts against the rails. The various Board of Trade inspections are referred to, and from the short interval which elapsed in each case between the inspection and the certificate, one gathers that the work was carried out to the satisfaction of this Government department. As an instance of the work involved during the year no fewer than 152 drawings, 271 tracings, 104 reports and statements, and 80 estimates for tramway work have been prepared

Digitized by Google

in the surveyor's department. In these totals parliamentary work is not included, and the plans of sections which have to do with the Sheffield Corporation Bill of 1900 have been the cause of much extra work in the department. The figures given in the report as to the cost of the work included are exceedingly valuable for reference. It is worthy of note also that the expenditure on tramways, which it is hoped will be authorised by the Bill of 1900, will be no less than £349,495. The other improvements included in the Bill are the revision of the building of streets regulations, the acquisition of land for sewage-disposal works, and the erection of artisans' dwellings, while the area of the city is proposed to be extended by no less than 4,003 acres. The surveyor adds that the large amount of engineering work and surveying which had to be done by his department for this Bill is responsible for the late issue of his annual report.

PROVISIONAL PATENTS, 1900.

DECEMBER 3.

21837. Improvements in prepayment electricity meters. George William Lummis-Patterson, 79, Percy-street, Newcastle-on-Tyne.

21838. An appliance or device for obtaining direct electrical impulses or currents from alternating electric sources. George Beckett Batten, 2, Underhill-road, Lordship-lane, London, S.E.

21852. Improvements in electric traction. Edward Henry Tyler and Arnold Greaves Hansard, 49, Queen Victoria-street, London.

21858. Improvements in or relating to electrical contacts for detecting electrical disturbances receiving electrical vibrations or like uses. Mathias Cantor and the Prof. Braun's Telegraphie Gesellschaft mit Beschränkter Haftung, 55, Chancery-lane, London.

21860. Improvements in electric meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

21861. Improvements in controlling electric boosters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

21862. Improvements in methods of securing pole-pieces to electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Henry G. Reist, United States.) (Complete specification.)

21880. Improvements in or relating to electrical governing or controlling apparatus. Ernest Francis Moy and Percy Henry Bastre, 37, Essex-street, Strand, London.

21886. Improvements in electrical storage or accumulators. Louis Ernest Lacroix, jun., 65, Chancery-lane, London.

21903. Improved means of holding the inner glass and lower carbon of an electric arc lamp. Frederick James Green, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21904. An arrangement of electrical resistance specially adapted for electric arc lamps. Frederick James Green, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21880. Improvements in and connected with wireless telegraphy. André Blondel, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, May 3, 1900, being date of application in Belgium). (Complete specification.)

DECEMBER 4.

21922. Automatically controlling the speed at which electric tramcars, motors, and the like may be driven. Robert Foster Collinge and Harold Henry Lindon, 54, Jolliffe-street, Liverpool.

21933. Improvements in electric arc lamps. Crompton and Co., Limited, Arthur John Hodgson, and John William Ewart, The Arc Works, Chelmsford. (Complete specification.)

21961. New or improved self-acting electric fire-alarm and signalling device. Friedrich Gülbling, 187, Albany-street, Regent's Park, London.

21962. An improved adjuster or height regulator and cord receiver for electric lamps and like purposes. Horace McGowan, 33, Cannon street, London.

21991. Improvements in connections for electrical conductors. William Bingham Cleveland, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22010. An improved method of connecting electrical conductors. William Bingham Cleveland, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22019. Improvements in storage batteries. Achille Meygret, 72, Cannon-street, London. (Complete specification.)

22021. Improvements in arc lamps. Joseph Velle and the Mercury Cycle Manufacturing Company, Limited, 72, Cannon-street, London. (Complete specification.)

22022. Improvements in or relating to secondary or storage batteries or accumulators. Alfred Julius Boult, 111, Hatton-garden, London. (Louis Sauvan, France.)

22026. Improvements in electric wave telegraphs. Alfred Julius Boult, 111, Hatton-garden, London. (American Wireless Telegraph Company, United States.) (Complete specification.)

DECEMBER 5.

22068. Improvements in the construction of instruments for the measurement of electrical energy. Arthur Cecil Heap, 21, Lee-park, Blackheath, London.

22098. Improvements in the production of electric light. James Weir Graydon and Johann Otto Egestorff, 77, Chancery-lane, London.

22116. A new or improved endless electric conveyor for conveying tin plates from the bath of molten metal to a suitable or desirable place. John Baxter, Oliver Clark, and Charles Hillman, 22, Glasshouse-street, Regent-street, London.

22126 Improvements in apparatus for wireless telegraphy John Ambrose Fleming and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery lane, London.

22142. A new or improved telephone relay. Emil Schack Hagemann and Valdemar Poulson, 18, Buckingham-street, Strand, London. (Complete specification.)

DECEMBER 6.

22182. Improvements in or connected with electrical contact makers or switches for use at the insulated junctions of sections of electrical tramways and railways and for analogous purposes. Hugh Godfrey Nicholson, 47, Lincoln's-inn fields, London.

22196. Improvements in electric arc lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification)

22197. Improvements in electric arc lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

22230. Improvements in or relating to electric cables or conductors. William John Glover, 6, Lord-street, Liverpool.

22233. Improvements in or relating to electric railways, tramways, and the like. Coleman Kandó, 18, Buckingham street, Strand, London. Complete specification.)

22234 Improvements in or relating to automatic electrical relays for operating pneumatic brakes in electrically-propelled vehicles and the like. Coleman Kandó, 18, Buckingham-street, Strand, London. (Complete specification.)

DECEMBER 7.

22240. Improvements in the electrolytic refining of metals. Sherard Cowper-Coles, 82, Victoria-street, Westminster, London.

22253. Improvements in and relating to electric switches for use in controlling motors. Edwin Thorley Parker, Prince's chambers, Wolverhampton.

22272. Improvements relating to galvanometers, voltmeters, and like apparatus. Thomas Edward Gambrell and Charles Thomas Gambrell, 17, Giltspur-street, London.

22273 Improvements relating to electrical plug resistance boxes and like apparatus and to switches therefor. Charles Thomas Gambrell and Thomas Edward Gambrell, 17, Giltspur-street, London. (Complete specification)

22281. Improvements in the means for suspending electroliers, electric lamps, and the like. Edwin Fletcher, 5, Corporation-street, Birmingham.

22285. Improvements in current collectors for electric vehicles. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Samuel B. Stewart, United States.) (Complete specification.)

22286. Improvements in electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William B. Potter, United States.) (Complete specification.)

22287. Improvements in synchronising apparatus for electric alternators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Fred T. Dow, United States. (Complete specification.)

22288. Improvements in means for attaching pole-pieces to electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Henry G. Reist, United States.) (Complete specification).

22290. Improvements in telephone and telegraph apparatus. Sidney George Brown, 9, Putney-hill, Putney, London.

22313. Improvements in manufacturing laminated cores for electrical apparatus. Aron Nicolaus Thorin, 322, High Holborn, London.

22316. Improvements in or relating to electric cables or conductors. William John Glover, 6, Lord-street, Liverpool.

22330. Improvements in alternate-current measuring and indicating instruments. William Morris Mordey, 46, Lincoln's-inn-fields, London.

NOTES.

Crystal Palace Engineering School.—The committee of directors of the Crystal Palace Company's School of Practical Engineering entertained a number of guests yesterday on the occasion of the announcement of the lists of certificates awarded by the examiners for the last term. Sir Douglas Fox, past-president of the Institution of Civil Engineers, presided, and both before and after the formal function the workshops and laboratories were open for inspection.

Municipal Electrical Association.—It will be remembered that this association decided last autumn that they would appoint a permanent secretary to look after the greater amount of routine work of their association. We are now informed by Mr. E. T. Ruthven Murray, the present hon. secretary, that the council have appointed Mr. C. McArthur Butler as their permanent secretary. The address of the association will in future be St. James's Hall, Piccadilly, and all communications should now be addressed to the new secretary.

Society of Model Engineers.—On Saturday, Dec. 15, by kind permission of Mr. A. Bromley Holmes, M.I.C.E., city electrical engineer, a party of members of the Liverpool branch of the Society of Model Engineers paid a visit to the Pumpfields electric supply station, which is practically the largest owned by the Liverpool Corporation, and of which a detailed description was given in these pages a few weeks ago. A library is being formed in connection with this branch of the society, similar to that of the London branch, and contributions will be gratefully received by the hon. secretary, Mr. F. T. Stewart, 14, Adelaide-road, Kensington, Liverpool.

Electric Tramcars as Post Offices.—It is hardly to an electric tramcar that one would look to post one's letters. Nevertheless, the authorities at Coventry have carried into execution the certainly novel idea of attaching letter-boxes to cars running into the city from outlying districts at night time. A very appreciable saving of time is thus gained, as letters may be posted on the cars at the various stoppages *en route* about two hours later than the dispatch from the local post offices. This part conversion of electric tramcars into post offices, we are told, is merely temporary, but, surely, would it not be a great benefit to the public if the plan were adopted permanently

One Hundred and Fifty-Three Mile Transmission.—Some interesting experiments were recently made by the Snoqualmie Falls Power Company, in which all the transmission lines of the company were connected up in series. Energy was then transmitted through the whole length, which amounted to 153 miles, and an electric motor was successfully driven through this length. We are not told, however, what the voltage employed was, but the experiment was made to see if any unexpected results occurred. What is wanted to be known, however, is whether a sufficiently high voltage can be used without trouble on the line to make transmission of power over such a distance economically possible.

The Paris-Rome Telephone.—We hear that the work of constructing the telephone line which is to bring France and Italy into close unity is making great progress, the connections with Paris on the French side of the Alps having already been completed. Operations on the Italian side, however, are even more advanced, for the installation, which for this particular part of the line cost only 100 million francs, has been made, and now the engineers are turning their attention to the erection of the line between Turin and Novi. After this it will be carried to Genoa, and thence along the littoral to the Italian capital. Paris and Rome, it is expected, will be in direct telephonic communication by March or April next.

Copper Electrodes.—In the latest edition of his book on "Medical Electricity," Dr. Lewis Jones recommends that electrodes employed in giving various kinds of electric baths should be made of copper for preference. With this statement Mr. Richard J. Cowen, L.R.C.P. (Ireland), cannot agree, for we notice that in a letter to the *Lancet* on the subject he states that electrodes made of copper "rapidly discolour and corrode under the influence of the products of electrolytic decomposition of whatever fluid is used for the bath, and consequently are troublesome." Mr. Cowen goes on to state that for the last two years he has used electrodes of thin sheet aluminium, finding them practically untarnishable in the solutions usually employed, and in every way much more suitable. The writer concludes by saying, for the information of those who use electric baths in their profession, that in the case of aluminium the terminals should be clamped on, as soldering the metal is difficult and unsatisfactory.

Glasgow Local Section.—The attendances at the two meetings that have already been held of the Glasgow local section of the Institution of Electrical Engineers have been so well attended that the committee have found it necessary to engage the large hall of the Institution of Engineers and Shipbuilders for their future meetings. It is fortunately disengaged for all except the January date, so that after that meeting, which will unfortunately have to be held in the small hall, the large hall will be utilised. At the first meeting in November, when Mr. Chamen read his paper, the small hall was so uncomfortably crowded that the committee engaged the large hall for the important discussion on Mr. Langdon's paper, which we print on another page, and seeing the number that turned up it is fortunate they did so. Mr. R. F. Yorke will read his paper on "The Utilisation of Water Power for Electrical Purposes" at the January meeting. The local hon. secretary tells us that the total membership of the section now numbers 118, and that there are nearly a score of new candidates up for election. One point of considerable gratification to the committee is the number of members of the Institution resident in other parts of Scotland whose business frequently brings them to Glasgow, and who appear to make it a special point of so arranging that they are there for the meetings.

London County Council Scholarships.—The *London Technical Educational Gazette* issued under the date of November last, which has just reached us, contained a number of regulations in connection with scholarships and exhibitions which will be awarded during the coming year. For instance, it deals with intermediate county scholarships, senior scholarships, art scholarships and exhibitions, evening exhibitions in science and technology, the Swanley horticultural scholarships, the junior scholarships in practical gardening, training scholarships in domestic economy, and also cookery. The large number of awards which are described in this issue, and the regulations in connection with which they are given, brings us again to the question as to whether the large amount of money which is given annually by the London County Council for scholarships and exhibitions is well spent. There are, for instance, 100 junior artisans' evening art exhibitions, each the value of £5; the value is not sufficient to enable the student to give up his daily work and to devote his time to perfecting himself in art, and we think that the money would be more usefully spent if it were divided up among fewer students. The same argument applies in other departments, and it

Digitized by Google

is our opinion that it would be more useful to put means of obtaining higher education in the way of a select few of the students than to give small doles, which get to be looked upon as a reward for past attainments.

A Corean Electric Railway.—The *Street Railway Journal* gives some interesting particulars of the Seoul electric railway, which is not only the first electric railway in Corea, but also the first railway of any kind to be built there. It extends from the Queen's Tomb, east of the city of Seoul, through the centre of the city, and beyond the southern wall to the Han river The main line runs through the east and south gates, while a branch line runs through the west gate, and nearly surrounds the terminal of the Seoul and Chemulpo steam railroad, which is located just outside the city walls on the south-west. The total length of the road is 10 miles, five miles of which are inside the city walls and five miles outside. An extension from the Queen's Tomb eastward to Toksoh, a great distributing centre six miles away on the Han river, is now being constructed. The road is owned by the Corean Government, but was built and is still operated by Messrs. Collbrand and Bostwick. The number of passengers per month average about 110,000, out of a total population of about 400,000. The road is divided up into six sections, the fare on each of which is about 1½d., or a charge of 7½d. is made for the whole journey of 10 miles. A speed of nine miles within the city walls and 17 miles outside is maintained. The prejudice of the people against the line, which led to the riots referred to in one of our previous issues, has now been largely overcome. It will be remembered that these riots were partly in consequence of a boy having been killed by one of the cars.

Improving the Load Factor.—A boot manufacturer in Switzerland is reported to have hit upon a novel means of improving the load factor of the plant which supplies electrical energy to his factory. This energy, it should be mentioned, is required principally for lighting purposes at night. With the exception of a comparatively small amount required for a motor load, most of the available power has hitherto been unutilised during the day, although a constant supply has to be maintained by the supply company, and paid for accordingly by the manufacturer. An arrangement has now been devised whereby it is proposed to remedy matters. Curiously enough, the idea was suggested by the abundant fruit harvest of the past season, and consists in no less novel an innovation than the artificial drying of fruit by means of heat generated by the surplus electrical energy. Apparatus has been constructed by means of which dried apple rings of excellent colour and quality have been produced. From a description of the apparatus which we have before us, it would appear that its arrangement is very ingenious. The apples are peeled, cored, and sliced by machinery, the rings being thereupon consigned to electrically-heated ovens of the travelling type, wherein the evaporation may be regulated to a nicety. Judging from the success which seems to have attended the experiment, it appears quite within the bounds of possibility that the method may find favour in such isolated cases where the local conditions are so eminently adapted. But of economy in such an arrangement there can be no question, unless water power be the prime mover available. Certainly the idea in no sense lends itself to a general solution of the load-factor problem, from which we are apparently as far off as ever.

Power Distribution in North London. — The North Metropolitan Electric Power Distribution Company, which in July last were granted powers to distribute electrical energy over a large area of the North of London, have this year been making applications for provisional orders for a number of the districts within their area. Under the terms of their Bill they can only supply in these districts with the consent of the local authority, and there are, of course, two ways open to them—*i.e.*, they can either supply in bulk to the local authority, who would distribute the electrical energy throughout the district, or they can supply to a subsidiary company holding a provisional order. In the case, however, of Stoke Newington, it seems that they have applied themselves, but the Electric Lighting Committee of the borough are strongly opposed to the granting of a provisional order to the company. The objection is based on the ground that, having obtained a provisional order, they could supply electricity in Stoke Newington without any agreement with the Borough Council, or supervision by them. These, of course, are points which can be overcome, and without doubt the company will make a further attempt to get the necessary consent within the prescribed time. The whole question turns round the cost of supply, and it must be remembered by the Borough Council that although they may be supplied in bulk at what seems to be a low figure, the mains necessary for distributing the energy will require a very considerable capital outlay, the interest charges on which will bring up the cost of the energy as delivered to consumers. In fact, in order to ascertain whether the company's proposals are advantageous, they must compare the cost per unit supplied in bulk with the works' cost of generation in other towns much of the same size. To be quite accurate, the interest charges on the cost of the central station and plant should be added to the works' cost when making a comparison.

New Alternating Arc Lamp.—The need of an alternating-current arc lamp to yield a hemispherical diffusion of light equal to that obtained with the continuous-current arc has led a well-known Continental firm to introduce a lamp which claims to conform to this requirement. The carbon rods of the lamp in question are inclined at an angle of about 50deg. relative to each other above the horizontal, whereby it is ensured that the available light with the exception of a small fraction is reflected downwards, the objectionable shadow cast by the lower carbon in a lamp of the ordinary type being at the same time avoided. However, the inclined position of the carbons does not of itself suffice to ensure the requisite diffusion, since experiments proved that carbons of the ordinary type when so inclined caused the arc to mount and flicker violently. This difficulty was overcome by an expedient simple in itself, but surprising in its efficacy—namely, by flattening the upper sides of both carbons. The fraction of the light rays which go upwards from the arc are reversed by means of a small reflector, while the two craters emit their light rays to the right and left of the vertical centre. Photometric measurements have shown that the hemispherical intensity of the light obtained with this new lamp exceeds by considerably more than half that yielded by previous types of alternating-current arc lamps, while the diffusion is also favourable to the new lamp, since practically the whole of the available light is reflected downward. For exterior lighting the lamp should be hung as high as it is usual to hang continuous-current arcs, so as to obtain uniform illumination at the ground level. In virtue of the inclined position of the carbons, constructional advantages accrue in that a globe of much smaller dimensions may be used. Further, there are no rods either below or at the side of the arc to cast objectionable shadows, nor are there any of those bands and chains which so frequently cause trouble

Digitized by Google

in the ordinary type of lamp. As a rule, the lamp is constructed on the differential principle. The requisite difference of potential between the terminals is from 29 to 30 volts, according to the current strength.

Starting Torque.—In connection with cable tramways, and also with moving platforms as installed in connection with the Paris Exhibition, the standing friction which has to be overcome in order to start the platform or heavy cable into motion is a factor not easily predetermined. We notice in the *American Electrician* that when a cable line in Kansas City was converted from steam-engines to electric motors some interesting experiments were made for the purpose of ascertaining what the starting torque would be. In this case the whole system of tramways was not converted to electrical working, but electric motors were used to drive the cables. The indicator diagrams taken from the engines in the usual way gave a fairly accurate means of determining what power would be required when the cable was running with the cars in regular service. It was necessary to ascertain what it would take to start the cable from a standstill under such conditions as would exist should a circuit-breaker open when the cable was in regular operation, and make it necessary to start up from a dead stop. To do this, a series of indicator cards were taken on the cable engine starting from a standstill with all the lost motion taken out of the gears. The engine crank was put at exactly half stroke, and steam was admitted to the cylinder gradually until the engine would just start the cable. The pressure shown on the indicator card at the instant of starting was noted, and this process repeated until a number of indicator cards were obtained. From this a fair average could be calculated. The torque exerted by the engine was then figured from the total steam pressure on the piston head at the instant of starting. From this the starting torque to be required from the electric motor when geared at the proper ratio to run the cable at normal speed was obtained, and this was compared with the torque the motor would exert when running at its rated speed and horse-power. Then by allowing a good margin for overloading the motor, the current required to start the motor and cable machinery from a standstill was determined.

Method of Charging.—The number of engineers who have devised new means for regulating the charges for electric energy for lighting and power is legion. The last system we have had brought to our notice is that devised by Mr. Ralph J. Patterson in the December number of the *American Electrician*. This gentleman starts with a correct basis, in that he proposes to charge all consumers a fixed sum per annum to represent the interest on the capital outlay required to supply them. He also makes this fixed charge dependent upon the maximum demand, but we do not see that he proposes any accurate system of determining the actual maximum demand. He suggests, however, that excess current cut-outs could be used to dim the lights if the maximum demand is exceeded, but this will not find favour with consumers. Besides this first charge a small charge of 2½d. per Board of Trade unit is also proposed, so that it will be seen the system is not unlike that which has been used in Manchester. What, however, we do object to is that Mr. Patterson proposes to vary the fixed charge per lamp per annum, and to make it dependent on the number of lamps demanded. Converting his figures into 8-c.p. lamps instead of 16-c.p., it seems he would charge a consumer demanding four lamps 10s. per lamp per annum, over and above which sum the consumer would have to pay for all energy supplied at 2½d. per unit. This fixed sum per annum per lamp falls down to 5s. if 20 8-c.p. lamps are demanded, and to 3s. per lamp if 50 8-c.p. lamps are assumed by the consumer to be his maximum load. It must be borne in mind that it is the lamps demanded at one time, and not the lamps fixed, which Mr. Patterson works with, and hence we fail to see why the capital charge should be reduced to larger consumers. It has been the experience in a number of electric light stations in this country that it is the small consumers taking, say, half a dozen 16-c.p. lamps whom it really pays the central station most to supply. We think, on the whole, that the system reviewed is much too cumbersome, and that it is, in consequence of its differential rates, inferior to the Brighton system, which uses maximum demand indicators to ascertain what the consumer actually takes.

Electrical Progress in Japan.—How wonderfully advanced Japan is in the practical applications of electricity may be gathered from a brief survey published in the *Zeitschrift für Elektrotechnik*, which reports, amongst other information, that the Japanese Government have sanctioned important railway extensions in the island. A number of new full-gauge lines, including a 20-mile stretch between Osaka and Kobe, and two other stretches having lengths of 18 and 13 miles respectively, some of which are already in course of construction, will be equipped for electric traction. An extension of the network of street railways connecting Tokio and the principal factories with the more important seaports is also proposed—this to be likewise equipped for electric traction. It is stated that Japan already possesses upwards of 400 electric generating stations, of which 19 serve solely to supply energy for working street, mine, and factory railways, while the remainder supply energy to towns and villages for lighting purposes, and to factories, etc., for both power and lighting purposes. Central supply stations having an individual output of 4,000 h.p. and upwards exist in Tokio, Kobe, Nagoya, Yokohama, and elsewhere. The motive power is supplied in each of these cases by steam. Considerable water power is also available. This is notably the case in Kioto, where a large turbine plant is driven by the waters of Lake Bitwa, also at Osaka, where the natural outlet of the same lake represents an available force of over 25,000 h.p., a portion only of which is at present utilised. Although Japan is making rapid headway as regards the manufacture of its own requirements, it is, nevertheless, an important market for electrical machinery, etc., of foreign manufacture, and especially in view of the traction work proposed is likely to remain so for some time to come. Most of Japan's railways run transversely across the country, and the island being of inconsiderable breadth, these lines are, therefore, admirably adapted for electric traction. But at some future date it is proposed to construct a line from the southernmost extremity of the main island *vid* Yeso up to the northernmost point of the same, thereby intersecting the transverse lines and so connecting the interior with the excellent harbours along the east and west coasts. It will, then, be seen that Japan bids fair to possess a model system of inter-communication, to the realisation of which natural conditions so strongly contribute.

Pacific Cable Surveys.—The work done not long ago by the American authorities on the survey of the Pacific Ocean to ascertain the best route for the proposed American Pacific cable has recently been reported on by Rear-Admiral R. P. Bradford, of the U.S.A. navy. This report has just been published, and the following information is extracted from it by our contemporary the *Electrical World*. It may be remembered that last year it was announced that submarine peaks and chasms were dis-

Digitized by Google

covered by the surveyors, and that the surveying ship "Nero" established the fact that a practical cable could be laid across the Pacific. Later last year and this year surveys have been conducted to discover a practicable route between Guam and Yokohama, Japan, and from Dingala Bay, Island of Luzon, to Guam. The zigzig survey from Dingala Bay to Guam was completed on Sept. 7 last year. The "Nero" sailed from Guam on Sept. 9, and arrived at Yokohama on Sept. 24, having run a line of soundings at close intervals between the two ports along a route 1,332 knots in length. After leaving Yokohama on Oct. 10, the "Nero" made a zigzag or traverse return survey to Guam, arriving there on Nov. 2. On Nov. 12 the zigzag survey toward the United States was resumed. It was completed to the Midway Islands on Jan. 3, 1900, and to Honolulu Jan. 29, 1900. Mention was made in last year's report of an obstacle in the nature of a submarine abyss on the route between the Midway Islands and Guam, not far to the eastward of the latter. The abyss, which is the deepest yet discovered in the world, was then only known to be of a greater depth than 1,900 fathoms. It now appears that, on the trip of the Nero to the westward, while attempting to sound, 4,913 fathoms—or 29,478ft.—of the sounding wire, all that was on the reel, were unwound without reaching bottom. Upon leaving Guam Nov. 19, 1899, on the trip to the eastward, Lieutenant Commander Hodges made further explorations in this locality, now known as the Nero Deep, which confirmed the previously announced conclusion regarding the necessity for deflecting the cable route from the Midway Islands to Guam, and added to the knowledge of the greatly depressed area already referred to. This region, the extent of which the survey has well defined to the north-eastward, afforded an opportunity for the "Nero" to make the two deepest casts and take the two deepest water temperatures ever recorded. The depths found were 5,160 fathoms and 5,269 fathoms, and the temperatures were 35·6deg. F. at 507 fathoms and 36deg. at 5,101 fathoms.

Lifting-Electromagnets.—The design of electromagnets for lifting heavy weights is confined to a few electrical engineers, and practical details in connection with this design are not readily available. We notice, for instance, in the *American Electrician* for December an article on the subject by Mr. E. B. Clark, who has evidently had considerable experience in the matter. Even this gentleman does not give any practical figures from an actual design, and his undimensioned drawing of a circular lifting magnet is of little service. His general conclusions, however, are interesting. He points out that for lifting steel plates of considerable length and width, the electromagnet, which is able to seize the plate in the middle and lift it clear of obstacles, has a wonderful advantage over rolling tables. There is certainly the danger that the plates might be dropped if the circuit through the electromagnets was interrupted, but the author rightly says that there is no reason why the route over which the plates have to pass should not be kept as clear of workmen as has to be the case in the older methods of transport. He states that in designing magnets it is not well to press the induction up to a point higher than gives about 150lb. pull per square inch of pole surface. The uncertain feature in their design is the air-gap between the faces of these poles and the iron to be lifted. It is, therefore, necessary to provide ample magnetomotive force in such magnets. When long plates have to be lifted, the circular form of pole-face is not to be recommended, as the iron is apt to bend, and hence tear away from the magnet. For instance, a circular magnet which will lift on a straight pull 10,000lb. easily will refuse to pick up a long thin plate which weighs only 1,000lb. In order to avoid this effect, a group of rectangular poles acting along the line of the bent plate is to be preferred. It is sometimes desired to alter the lifting power of the magnets so that they will only hold one of a number of articles. The author does not advise reducing the current through the magnets in order to do this, but states that by rapidly switching on and off, the operator can cause the magnet to drop all but one of the articles. It is also important with these lifting magnets to have a discharging resistance to take the throw when the circuit is broken. For this purpose it is well to shunt the electromagnet by introducing lamps in parallel, which should have a capacity about 50 per cent. more than the current absorbed by the amgnet. The voltage of the lamps should also be rather more than that of the supply circuit. The only guide given to current consumption is the statement that an electromagnet for handling plates weighing 3,000lb. should be easily operated by 1,000 watts. Under favourable circumstances these magnets will then lift considerably more than the load mentioned above.

Municipalities and Income Tax—The litigation between the London County Council and the Crown, which was commenced some years ago with the view of determining the Council's liability in regard to the payment of income tax, has recently culminated in a judgment of the House of Lords in the Council's favour on all issues. The Council's case was that it was wrongly asked to pay the tax twice over upon the same revenue, and apparently this was the view taken by their lordships in the House of Lords. The fund out of which the dividends are paid to the stockholders, it would seem, consists principally of interest, rents and rates received. When the Council pays these dividends it deducts income tax, and the question raised was as to how much of the tax so deducted the Council was entitled to retain. The Crown originally claimed the whole of the tax deducted from the stockholders dividends, but in the course of the proceedings they moderated their contention by admitting that the Council was entitled to retain some proportion of the tax in respect of the interest item. But this was not enough for the London County Council, and the case was fought out on the issue that the Council was entitled to some proportion of the tax in respect of rents as well as interest. Income tax on the interest and rents was already paid before coming into the hands of the Council, and therefore the Council took up the position that they had a right to retain so much of the tax deducted from the stockholders' dividends as was equivalent to the tax so paid, otherwise it would be paying income tax twice over upon the same moneys. The House of Lords was unanimously in favour of the Council's contention, and reversed the decisions of the inferior courts in the case. The Council are to be warmly congratulated on this success, for the question is one to which the greatest interest and importance attach. The highest tribunal has in effect decided that bodies, whether municipal or otherwise, are not liable for income tax on revenue which they receive in respect of interest and rents, because the tax has already been paid on these moneys. If the Crown had succeeded even on its modified contention, the Council would have had to pay over to the Inland Revenue authorities no less a sum than £32,000, and, of course, the tendency would be for this sum to increase as the Council's financial operations grew. Between 1892 and 1897 the Council paid all the tax deducted from the dividends, and also tax on the interest and rents, but a summarised claim for all sums, which, it contended, had been overpaid, amounting in all to £71,686, was sent to

Digitized by Google

the Inland Revenue Office. Shortly afterwards it was agreed that the tax payments for back years should be adjusted on the basis of the final decision of the Law Courts, so in the long run the Council will not be the losers. A difficult and complicated question of far-reaching effect has thus been finally settled, and the necessity for litigation on the subject, it is to be hoped, will be considerably lessened in consequence.

The Paderno Transmission Plant.—We notice in the *Electrical World* an interesting *résumé* and investigation of the working of the Paderno transmission scheme by Mr. G. Semenza, who has had so much to do with the engineering details of the scheme itself. The interest in this plant is due to the fact that it represents conditions which will apply in a great many power transmission schemes. In the first instance, no less than 4,000 kw. of plant are provided, the transmission line being 25 miles long. One most important point is that the generators produce a higher voltage than is commercially used elsewhere. In this instance no less than 15,000 volts were generated in the three-phase circuit's armatures, and it seems that the machines are getting successful results. Our contemporary in America, however, is rather sceptical as to the advantage of generating such high voltage direct in the armature of the alternator. It holds that it is rather apt to encourage resonance effects if the machines are constructed in the usual way, because it is not easy to obtain a wave form which is nearly a sine current. In consequence of this there are harmonics developed which may cause trouble on the line or in the machine. The Paderno machines, however, seem to have good regulation on non-inductive loads, but they are somewhat sensitive to inductive loads. On the transmission line there has been considerable trouble with lightning, in spite of the use of iron poles and lightning arresters. In fact, on two occasions the works have been shut down from lightning discharges. Another interesting feature of Mr. Semenza's report is the very careful investigation of the power factor of the load. The very large use of synchronous motors in the Paderno plant is striking, and the result is highly satisfactory, so far as the power factor is concerned. The induction motor part of the load seems to give about the same results as are found in similar cases in American practice, and the same difficulty of underloaded motors seems to have been encountered. If induction motors are worked somewhere near full load little trouble with lagging current is met, but if many of them are habitually worked underloaded the case may be quite different. The synchronous motors employed for driving dynamos and worked with over-excited fields, seem to have acted as an almost complete corrective of the inductive load elsewhere, so that the net result of 0·91 for the power factor of the system is excellent, particularly when one considers the effect of the reducing transformers. Synchronous motors form a convenient and useful part of most transmission systems, but we know of few cases in which they are so advantageously used on so large a scale as at Paderno. The author has also devoted considerable attention to investigations on the line, in which no less than six complete three-phase circuits are provided. The impedance factor of the line was found to be 1·35, while the charging current proved to be 1·03 amperes. The author succeeded in separating out this last figure into leakage and capacity components. He found that the leakage was not quite a quarter of an ampere, which is exceedingly good considering the high voltage used and the length of the line.

Electric Traction in Italy.—A paper recently read in Paris by Mr. Tremontani, and reproduced in *L'Elettricista*, contains some interesting information about the full-gauge railway line between Milan and Gallarate, which is being equipped for electric traction. The line has a double track and is 25 miles long. Three single-track lines branch off from Gallarate; one, having a length of 16 miles, going to Arona, a second, 19½ miles long, to Lugano, and a third, 21 miles long, to Porto Ceresio. All these lines are at present worked by steam locomotion, but after the introduction of the electric service the steam hauled trains are to be entirely dispensed with. A 12-minute service of trains will be run in each direction over the main line, some of the trains being express, while an hourly service in each direction will be inaugurated on the branch lines. It is proposed to provide 20 motorcars and a like number of trailers, the first-mentioned to accommodate 75 and the trailer 99 passengers each. The motors are of the two-bogie type, and will be equipped with four motors each. The express trains are to accomplish the distance between Milan and Gallarate in 30 minutes, which corresponds to a speed of 50 miles per hour. All calculations relating to current consumption have been based on an estimate of 104 watt-hours per ton-mile. The necessary power for working the line will be generated and transmitted in the form of multiphase currents, and afterwards converted into direct current for the motors. As a site for the power station Tornavento has been selected, which is situated at a distance of seven miles from Gallarate. Water will ultimately be the prime mover, of which 11,000 h.p. is available from the River Tessin. Having regard, however, to the considerable time which the necessary hydraulic work will take to complete, an auxiliary steam plant is being put down, which later on will be held in reserve. The steam-engines, three in number, are of the tandem compound condensing type, with a maximum output of 2,000 h.p., each being coupled to a 750-kw. multiphase generator. The current, generated at an initial pressure of 13,000 volts, is transmitted to Gallarate by means of two overhead circuits of 7·8mm. wire, there being consequently six high-pressure wires in all. Provision is also made for five sub stations to be equipped with transformers and rotary converters. In three of these sub-stations will be placed two converters of 500 kw. capacity, and in each of the remaining two a converter of 250 kw. capacity. The overhead feeders are suspended parallel to the railway at a distance of 16ft from the track, while the height of the lowest wire above the ground level is 23ft. But where tunnels occur these high-pressure feeders are diverted from the railway. Wooden poles, provided with wooden cross-arms, are used to carry the feeders These poles are placed at intervals of 130ft., and, contrary to American practice, iron pins are employed to support the insulators. Each pin, however, has a porcelain cap, and upon this is mounted the insulator proper. The distance separating individual wires is 20in., while the loss in the high-pressure lines is estimated at 1·8 per cent. But the mean efficiency of the transmission line from the switchboard in the generating station to the collectors of the motorcars is estimated at 80 per cent. The converted current, at 650 volts pressure, will be conveyed to the motorcars by means of a third rail. This has the form of an ordinary Vignoles rail, and weighs 91lb. per yard. It is laid in 39½ft. lengths upon special insulators, at a distance of 2ft. 2½in. from the nearest running rail. The joints are made with fishplates and electrically bonded. Two collector shoes are provided at each side of a motorcar—one pair for each direction of travel. At crossings and points the third rail is, of course, interrupted. Underground cables are employed at such points to maintain the electrical circuit. The bearing rails serve as a return conductor in the usual way.

THE PHILOSOPHY OF DYNAMO DESIGN.

(Specially contributed.)

(Continued from page 839.)

Limits of Load.

It has been already stated that there are two factors which govern the output of a dynamo—viz.: firstly, the rise of temperature in the armature due to the flow of the current, and which, considering R_a to be constant, will vary as C_a^2, where C_a represents the total armature current; and, secondly, the difficulty of obtaining such a position for the brushes as the load increases as will enable the short-circuited coils to be in a field of the requisite strength for sparkless commutation. The difficulty would be one easily overcome were we only concerned with the heating of the armature, as it would be a very easy matter to rewind a given size of core with a larger gauge of wire in order to increase the current output; and as the heating effect varies as $C_a^2 R_a$, and the resistance varies inversely as the area of the wire, by a suitable selection of the gauge of the wire the heating could be kept within any specified limit for any given output. But when we come to consider the question of sparkless commutation, we find that this easy method for increasing the output of a dynamo is not sufficient, and that more radical alterations are requisite, as the whole question of sparkless commutation is dependent upon the theory of the armature reactions.

The principles upon which the modern theory of commutation and armature reactions is based were first enunciated in the "Original Papers on Dynamo Machinery" by Drs. J. and E. Hopkinson in 1886, and were further developed at the meetings of the Institution of Electrical Engineers in January and February, 1890, when two papers were read—one by Mr. Swinburne on "The Theory of Armature Reactions in Dynamos and Motors," and the other by Mr. Esson on "Some Points in Dynamo and Motor Design"—and at a further meeting in April, 1891, when Mr. Esson read another paper on "The Design of Multipolar Dynamos"; and it is from these papers and the discussions which followed their reading that we have obtained almost the whole of our present-day knowledge of the armature reactions and the causes which limit the output of any armature; and it is only as they are in accordance with the principles which the authors of these papers laid down that the various devices which have been adopted to overcome the armature reactions are of value.

We have already seen that the magnetising force of the armature may be resolved into two components—viz., that due to the cross ampere-turns and that due to the back ampere-turns—and that the relative values of these two sets of turns will depend upon the position of the brushes; if the short-circuited coils lie upon the vertical diameter (in Fig. 31) there will be no back ampere-turns, while if they lie upon the horizontal diameter there will only be back ampere-turns and no cross ampere-turns. Consider Fig. 31, where X X represents the horizontal diameter and A C are two points taken at equal distances above and below it, then the magnetomotive force of the cross ampere-turns between these two points is proportional to the number of coils which lie between them, and if we join A O, C O, and call the angle formed by these lines α, and the total number of conductors on the armature τ, the number of conductors lying between A and C for any value of α will be $= \tau \times \frac{\alpha}{360}$, and the number of cross ampere-turns will be in a bipolar machine $= \frac{C_a}{2} \times \tau \times \frac{\alpha}{360}$, since half the armature current passes through each conductor, and the magnetomotive force of the cross ampere-turns will then be $1{\cdot}256 \times \frac{C_a}{2} \times \tau \times \frac{\alpha}{360}$. The lines of force due to this magnetising force will flow, as shown in Fig. 7, through the iron of the core, across the air-gap, through the iron of the pole-piece, and across the air-gap again into the armature core. If the induction of the iron is not so great as to saturate the iron, very little magnetising force will be requisite to force the lines through the iron, and the whole of the force may be considered to be utilised in propelling the lines across the two air-gaps, or along a length $2 l_g$, where l_g is the distance between the iron of the armature core and that of the pole-piece. If, as will be the case with a well-designed dynamo, the positions of A and C are close to the polar horns, the lines of force due to the cross magnetising turns will, as shown in Fig. 9, flow in the opposite direction to the lines of force due to the field at the leading horn, and in the same direction at the trailing horn. If A t_g equals the field excitation which is expended over the air-gaps, then the magnetomotive force due to the field coils on each air-gap will be $1{\cdot}256 \frac{A t_g}{2}$, and the total magnetomotive force at A and C respectively (Fig. 9) will be

at A $$1{\cdot}256 \left\{ \frac{A t_g}{2} - \frac{C_a}{2} \times \frac{T}{2} \times \frac{\alpha}{360} \right\},$$

at C $$1{\cdot}256 \left\{ \frac{A t_g}{2} + \frac{C_a}{2} \times \frac{\tau}{2} \times \frac{\alpha}{360} \right\},$$

and the induction B_g will vary between A and C within the limits of

$$B'_g = \frac{1{\cdot}256 \left(A t_g - \frac{C_a}{2} \times T \times \frac{\alpha}{360} \right)}{2 l_g},$$

and $$B'_g = \frac{1{\cdot}256 \left(A t_g + \frac{C_a}{2} \times \tau \times \frac{\alpha}{360} \right)}{2 l_g}.$$

In other words, as we have seen before, the induction under the trailing horns is as much increased as it is decreased under the leading horns.

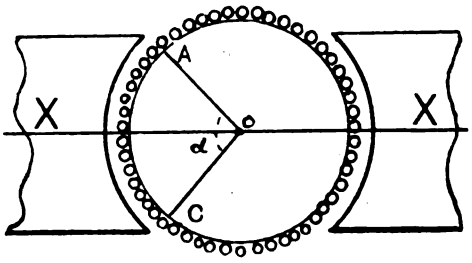

Fig. 31.

Now, the magnetising force of the back ampere-turns is proportional to the number of coils included in twice the angle of lead, and if λ = lead of brushes it will be equal to $\frac{C_a}{2} \times \tau \times \frac{2\lambda}{360} = C_a \times T \times \frac{\lambda}{360}$. But with a compound-wound machine we may consider that the series winding will increase the field excitation over the air-gaps by exactly the same amount as it would be reduced by the back turns, so that these turns may be left out of the question.

We have already seen, when dealing with the theory of commutation, that the short-circuited coil must be in a field of sufficient strength to produce in the closed coil a current equal to that flowing in the series of coils into which it is about to enter, and we have also just seen that the induction at the leading horn $= \frac{1{\cdot}256}{2 l_g} \left\{ A t_g - \frac{C_a}{2} \times \tau \times \frac{\alpha}{360} \right\}$. Now, if the output of the machine is too high, $\frac{C_a}{2} \times \tau \times \frac{\alpha}{360}$ may become equal to, or greater than, $\frac{A t_g}{2}$. In the first case there will be no field at all, and in the second case the flow of the lines of force will be in the wrong direction. In either event there would be such disastrous sparking as would prevent the dynamo being used at such a load; so that the output of the dynamo is, independently of any heating effect limited by the fact that $\frac{C_a}{2} \times T \times \frac{\alpha}{360}$ must be something less than $\frac{A t_g}{2}$. Let $A' t_g$ equal the excitation required for the field induction over one

Digitized by Google

air-gap, or $A' t_g = A t_g \div 2$. Messrs. Hawkins and Wallis in "The Dynamo" give as the limiting value for safe working of the above factor that it shall not be more than $\frac{A' t_g}{1{\cdot}5}$ for drum armatures and $\frac{A' t_g}{2}$ for Gramme armatures. Accepting these figures, we get for a drum armature

$$\frac{C_a}{2} \times \tau \times \frac{\phi}{360} = \frac{B_g \times 2\, l_g}{1{\cdot}5 \times 1{\cdot}256}$$

$$\frac{C_a}{2} \times \frac{\tau}{2} = \frac{B_g \times 2\, l_g \times 360}{3{\cdot}768 \times a}$$

$$= \frac{96\, B_g \times 2\, l_g}{a}$$

and for a Gramme armature

$$\frac{C_a}{2} \times \frac{\tau}{2} = \frac{72\, B_g \times 2\, l_g}{a'}.$$

It must be noted that in a bipolar dynamo the magnetising force which we have been considering above is that equal to half the total armature current multiplied by half the total number of inductors. This is evident from the fact that we have only been dealing with one pole-piece, and similar reactions occur upon the other side of the armature. Mr. Esson calls the product of the number of inductors multiplied by the current flowing through each the volume of current carried by the armature, and this will be, of course, double the amounts given above—viz.:

$\frac{C_a}{2} \times \tau$ will equal $\frac{192\ B_g \times 2\, l_g}{a}$ for drum armatures; and

$\frac{C_a}{2} \times \tau$ will equal $\frac{144\ B_g \times 2\, l_g}{a}$ for Gramme armatures.

Upon examining these equations it is seen that the volume varies directly as the induction, and as the length of the air-gap, and inversely as the angle a, or since a will be approximately equal to ϕ (the angle of polar embrace), the volume varies inversely as ϕ. So that in order to increase the output, the induction and air-gap must be increased or the polar embrace decreased. But if we desire to build an efficient dynamo, these alterations cannot be made to any great extent, and the output for a given size of armature, although it may be increased, will be found to have a limit.

Messrs. Hawkins and Wallis assume that the radial depth of iron of the core for drum armatures is 0·28 of the diameter, and that the induction is 14,500 in the armature; and, further, that the length of the air-gap is 0·0365 of the diameter of the armature. Then, substituting these values, we get for the limiting value of the volume,

$$\frac{C_a}{2} \times \tau = 600\ D \text{ for drum armatures,}$$

where D is the diameter of the core in centimetres.

Similarly we get $\frac{C_a}{2} \times T = 400\ D$ for Gramme armatures if we take the radial depth as ·2 D and $B_a = 18{,}000$

Mr. Esson in the paper he read in April, 1891, gives these figures, which he obtains somewhat differently. Let v = volume of current, or what we have expressed by $\frac{C_a}{2} \times \tau$; ϕ = the angle of embrace; l_g = length of air-gap; and B_g induction per square centimetre in the air-gap.

If, then, the armature is so loaded that the cross induction and forward induction exactly balance each other under the leading horns, we have $\frac{v\,\phi}{360} = \cdot 8\ B_g \times 2\ l$, and upon simplifying this we shall get $v = \frac{576\ l\ B_g}{\phi}$. Mr. Esson suggests that since it would be folly to run a machine at such a load that the slightest increase might ruin the commutator, this should be considered as the absolute limit, and that for practical purposes we should have a factor of safety of 2, and take as our safe working load

$$v = \frac{288\ l\ B_g}{\phi}.$$

If r = radial depth of core, w = width of pole-piece, and B_a the induction in the armature, $B_g = \frac{2\, r\, B_a}{w}$, and substituting this value in the equation, we obtain

$$v = \frac{576\ r\ B_a\ l_g}{w\ \phi}.$$

Taking the induction in the armature as 18,000 C.G.S. per square centimetre and ϕ as 122deg., we obtain

$$v = \frac{r\ l\ 85{,}000}{w}.$$

If we now insert the values in terms of the diameter for r and l we have previously used and take $w = 1{\cdot}5$ D, we shall obtain for Gramme armatures

$$v = \frac{\cdot 2\ D \times \cdot 0365\ D \times 85{,}000}{1{\cdot}5\ D} = 413\ D,$$

and for drum armatures

$$v = \frac{\cdot 28\ D \times \cdot 0365\ D \times 85{,}000}{1\ 5\ D} = 572\ D,$$

which practically agrees with the figures previously obtained of 400 D for Gramme armatures and 600 D for drum armatures; and as the values given for r, l, w, and ϕ in the above equations cannot possibly be absolute for all makes and types of dynamos, there must be a certain amount of elasticity in any formula, and, therefore, we may take these values, 400 D and 600 D, as our working rule for the absolute limit of load for all practical purposes.

It will be readily seen that while the question has only been dealt with so far as applying to bipolar machines, it is easy to extend it to multipolar types. In obtaining the equation $v = \frac{576\ l\ B_g}{\phi}$, we were concerned with one pole of the dynamo only, and this equation will hold good for one pole if the number of poles be increased to four, six, or more, for as the number of poles is increased the value of the angle ϕ must decrease.

The student will notice that the limiting output is less for a Gramme-wound armature than for a drum. This is due to the fact that there is a greater liability to sparking with a Gramme than a ring. The primary cause of this is that the resistance of two coils of a Gramme machine is, with well-designed dynamos, greater than the resistance of one complete coil of a drum armature owing to the greater length of wire necessary, while the number of face or active inductors is the same in the two cases, hence a stronger reversing field or greater lead will be required with the Gramme. The self-induction of a coil of a Gramme armature will also be greater, as both the external and internal lengths will carry the current, which has to be stopped and reversed; and as these are wound round the iron of the core, unless the forward induction in this part of its path is pushed well up to the saturation point, the self-induction will be of very great magnitude, consequently it is usual to work with a much higher induction in the core of a Gramme armature than in that of a drum. This will explain why in our equations for the limiting value of the output of a dynamo we took $B_a = 18{,}000$ for a Gramme armature and $B_a = 14{,}500$ only for a drum.

In calculating the magnetising force required, and the induction in the various parts of the path, the student must remember that there will be a certain amount of leakage of the lines of force, and only a proportion of those passing through the magnets and yoke will travel through the armature core. The calculations necessary to obtain the amount of leakage are long, and when completed can only be approximations, as much must depend upon the type of the machine, upon whether the poles are let into the bed-plate or kept a long distance away, upon the shape of the poles and magnets, and the proximity of other masses of iron, such as the bearings, flywheel, or coupling, in addition to which a small variation in the permeability of the iron or steel, as compared with that of the magnets of machines already tested, will require a greater alteration in the excitation than would a large error in the calculation of the leakage coefficient. The usual practice is to employ a leakage coefficient which has been obtained, not by laborious calculation, but by noting in previous machines of a

Digitized by Google

similar type what was the additional excitation required in order to obtain the specified E.M.F. at the stipulated speed, beyond that which would have been necessary were there no leakage.

With slotted or perforated armatures and multipolar machines the leakage will be considerably less than with smooth-core armatures, owing to the air-gap being considerably reduced in length, as many makers now give an air-gap of only little more than sufficient length to allow free clearance for the revolving armature.

The use of slotted cores has now become very general, and it is worth while to point out some of the advantages and disadvantages of this type of armature. The chief advantages are the small air-gap necessary and lower reluctance in the magnetic path (with consequent saving in field excitation), the positive driving of the inductors, the greater mechanical protection of the winding, the prevention of Foucault currents in the inductors, and the lessening of the field distortion between full load and no load. The chief disadvantages are that eddy currents are set up on the polar faces by the teeth, the increased self-induction of the short-circuited coils (owing to their being embedded in the iron), and the increased cost of manufacture. The proper number and size of the slots can only be obtained by compromise, as, owing to the tendency of the teeth to create eddy currents on the polar faces, shallow slots and narrow teeth should be used; while in order to reduce the hysteresis loss in the teeth, narrow slots and wide teeth should be employed; and, also, to reduce the magnetic reluctance of the teeth, the area at the bottom should be as large as possible, and consequently the teeth should be made as wide as possible, and the slots deep and narrow. The most suitable proportions can then only be obtained by experience and the careful noting of results obtained from different armatures, or, failing this, the information must be obtained from tables such as those given by Mr. Wiener in his "Dynamo-Electric Machines."

(To be continued.)

PRACTICAL NOTES ON ELECTRIC MAINS.

BY A MAINS ENGINEER.

(Continued from page 841)

Solid-laid systems take up much less room than conduits, although it is at times quite difficult enough to find space for these on the footway. If there should be insufficient room, however, the troughing can be taken into the roadway and laid at a much less depth than that at which it would be possible to lay a conduit, as it will take no harm from the compression due to traffic, simply because it is a solid system. If it is found necessary to take the troughing into the roadway and the cable is to be used as a distributor, care must be taken to lay it so deep that the top covering of the service cables tapped off the main does not come at a less depth than 2ft. from the surface of the road; this would make the main about 2ft. 6in. deep—say 2ft. 8in to the bottom of the trench.

The chief materials in use for troughings for solid systems are wood, iron, and earthenware. Wood troughing, if used, should be creosoted or boiled in Stockholm tar, but it does not make the most satisfactory job that one could wish for; it certainly does not seem right to bury wood in the ground and expect it to be a lasting thing. The use of wood also entails a lot of cutting with a saw—in fact, it requires almost a joiner to manage it properly so as to make a good job of the angles and bends; also it is not much use to expect the wood to act the part of an insulator, as the bitumen in which the cable is laid, or, rather, with which the trough is filled, is very often nearly dead earth, or giving very low insulation resistance indeed. From experiments made with wood troughing to try its lasting properties when buried in earth, it has been found to last longer in wet clay, a shorter time in dry clay or loam in which roots of trees abound, and a shorter time still in sand. This is probably because air does not find its way through the wet clay, the other two conditions giving it an easy passage. If wood is used, at the junction of every two lengths of troughing, whether short or long lengths, there should be fixed underneath a saddle or junction piece so as to prevent the ends of the troughing from sinking out of place, and thus causing a strain on the cable immediately over such junction. This junction piece should be at least 1ft. long, the grain of the wood running along its length; thus it will stand no chance of being broken after it is laid.

Care must be taken when laying troughing that it rests well on the bottom of the trench along its whole length, the junction pieces being let into the ground where they are required. If this is not done, the ground above will continue to sink for some time after being filled in, at the same time straining the cable. Owing to the spring of wood, this is more important with wood troughing than with iron or earthenware. The wood used for troughing should be at least 1¼in. thick, and after the cable has been laid ground should be filled in about 6in. deep; then another plank of prepared wood should be laid immediately over the troughing as a warning to people opening the ground afterwards. It is always well to use this warning plank if iron or earthenware troughs are used.

Troughs made of cast iron should be coated with a preservative coating, such as Dr. Angus Smith's compound. The iron should be at least $\frac{3}{16}$in. thick, and each length of troughing should be socketed at one end so that the following length will fit into this socket, the two being then bolted together with a countersunk headed bolt, the head of which will come a little below the level of the bottom of the troughing inside, a nut being placed underneath. Iron troughing in ground that is much crowded with pipes gives a lot of trouble in cutting, and joints are never well made. It would be well if makers of iron troughing would keep in stock bends and angle-pieces for several different angles and radii. The bends and angle-pieces should be made in both planes—*i.e.*, vertical and horizontal; they should also be made left handed and right handed. The engineer would then be able to order a percentage of these bends over the total length of the troughing required. When using iron troughing, the cable gang should be provided with a small bench drilling machine, plenty of three-faced files and cold chisels, flat and diamond pointed.

Earthenware troughing would last longer than either iron or wood, and certainly would offer the best resistance (electrical) between the cable and earth. Each two lengths of such troughing ought to fit together by self-locking socketed joints.

As to the class of cable to be used on solid-laid systems, almost any insulation can be used, and the cable may be lead-covered whether continuous or alternating supply. Rubber insulation, because it has given so much trouble in many places, might well be left out of the question, the preference being given to fibre, paper, or vulcanised bitumen; the first two probably would give the best results. If the cables are not lead-covered, they should be strongly protected with braid or tape to prevent damage when being drawn in.

When the trench is ready and the troughing has been carefully bedded and swept out, the cable should be drawn along in the troughing before the cable bridges have been placed in position, a man being stationed at every bend or angle in the run to prevent the cable being unduly rubbed. Two men can then easily place the bridges, one lifting up the cable and the other placing them at equal distances, varying according to the size of the cable. The bridges should never be more than 2ft 6in apart, even for the largest cables. A most important point when laying cables on the solid system is to see that the bitumen gets all round the cable as nearly as possible. The bridges should be designed to assist this as much as possible. If the radius of the hollow in the bridge is made much greater than the radius of the cable, the best form will be obtained, as the cable will then only touch the bridge on a very small surface. The minimum thickness of bitumen should be ½in., the troughing being designed to this end. The bitumen leaves the boilers at a temperature of about 450deg. F. It is then to be stirred and cooled by pouring into smaller pouring buckets until it has reached a temperature of about 350deg, at which heat it is poured into the trough. It is almost absolutely necessary that fine weather should prevail while cables are being laid on this system, and if rain should come on the cables must be wiped and allowed to dry before bitumen is poured on, as if they are wet the bitumen will not adhere, and a small channel is thus left between the

Digitized by Google

cable and the bitumen. A great benefit to be derived from a solid-laid system is owing to the fact that when a fault occurs, however bad, it is nearly always possible to burn it out without shutting down, as the bitumen in the trough is melted and runs into the fault, so offering some resistance on which to run; this takes place more easily when single-conductor cables are used.

Armoured cables take up less space than any other system, and room can nearly always be found for them on the footway. It is probably the cheapest system to use, as a great length of cable can be got in in a little time. It is also such a flexible system that pipes and drains offer very little, if any, obstruction, and cellar-roofs can always be negotiated by cutting away a narrow channel through the arch, a cast-iron pipe being then laid in the channel and the cable drawn through the pipe, the whole being then concreted solid. All armoured cables should certainly be concentric cables and lead-covered. The armouring and the lead covering would, however, be liable to be attacked by electrolysis if used for continuous current; this system is therefore better for alternating-current supplies. Fibre or paper-insulated cables give excellent results on this system.

When the cables are laid on the footway and after they have been drawn in, the soil should be sifted over them until they are covered by about 2in.; they may then be protected by new bricks laid on the flat, the length of the brick being placed across the trench. Bricks used thus form a much more flexible covering than planks, though planks should be used wherever possible. The bricks being new will never quite lose their new look, and will thus warn any people opening the ground. If the cables are laid in the roadway they should be laid at least 2ft. 6in. deep, earth being again sifted over them and covered by stout planks if possible, if not, then by new bricks as before, but placed on their edges in this case.

Armoured cables ought never to be laid direct in clay, as the clay, or the salts in it, often eats away the armour. In case clay is found, it is well to throw sand along the bottom of the trench to a depth of about 2in. before the cables are drawn in, then to cover the cables with more sand; this sand is never lost. Another way to stop the action of clay is to lay the cables on a sort of solid system, the troughing being made in this case of unprepared wood—*i.e.*, just rough sawn and of sufficient size inside to allow about ¼in. of bitumen to adhere round the cable. If the wood soon rots it does not matter, as the bitumen is still left to protect the cable or cables. Bricks should be used as a protection. If this system is adopted and more than one cable is laid in one trench, then room must be left between the troughings to allow joint-boxes to be fixed. Rough wood bridges should be used in this troughing also. This semi-solid system has been used at Cheltenham with excellent results. A gang of about 25 men can easily lay and cover up a trench 200 yards long into which four cables have been drawn in one day if the trench is on the footway, and a proportionally smaller length, according to the hardness, if on the roadway.

(To be continued.)

THE BARMEN-VOHWINKEL SUSPENDED RAILWAY.

(Concluded from page 844.)

In the suburbs, where the track is suspended over the roadway, the vertical supports are placed in line with the rows of trees to either side, so as to obtain minimum unsightliness. As regards the elevation of the super structure above the road level, an important limiting factor consists in that no constructional work in the shape of cross ties is placed below the level of the car floor. Compared with elevated railroads of the ordinary type, the height of the station platforms above the road level may be lessened by the amount corresponding to the depth of the permanent way plus the height of the car wheels. In fact, the height of the platform need not exceed 15ft., which corresponds to the height of the lower edge of the carriage above the road pavement. The girders which support the permanent way have the form shown in Figs. 8 and 9. All the vertical forces which come into play are taken up by the centre girder, *a b*, which is supported on bearings spaced at intervals of 10ft., while the lateral and torsional strains are provided for by the horizontal girders, *c d* and *e f*. As shown, the booms of the lower horizontal girder, *e f*, are formed by rail bearers, *e* and *f*. The ties, *a e* and *a f*, serve to transfer the vertical forces acting at *e* and *f* to the girder, *a b*. This method of construction was invented by Rieppel. The weight of the ironwork is relatively small. For the Wupper section, where the railway has a span of about 98ft., the weight of the ironwork amounts to only 1 ton 2cwt. per yard run,

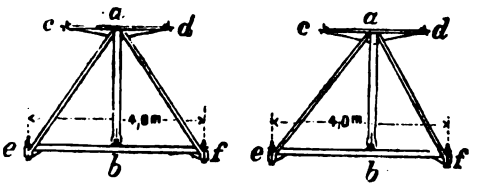

FIG. 8.—Details of Permanent Way.

and for the land section one ton. These weights are considerably less than those holding for elevated railways of the ordinary type. The arrangement of the superstructure also facilitates the inspection and maintenance of the same. There is a space of 13ft. between the rails, but half only of this space is covered in, whereby sufficient provision is made for the inspection of the rail tracks and conductors, while at the same time undue darkening of the roadway is avoided. Each car is suspended from the track in the manner shown in Fig. 10. The frame, *r*, of the suspension arrangement is bent round the rail

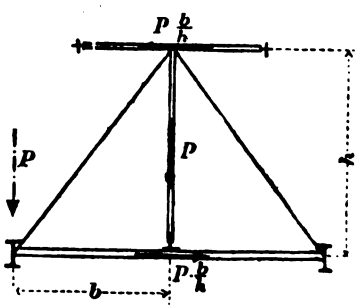

FIG. 9.—Details of Permanent Way.

carrier, *t*, in such a way as to leave very little play between the bevelled undersurface of the latter. By virtue of this arrangement, not only is the lifting of the driving wheels from the track rendered impossible, but also a detachment of the car from the track consequent upon an axle or other part breaking also rendered inconceivable. It is, however, apparent that the round railhead of the track constitutes a centre about which the car can oscillate. In this connection it was at first a matter of some doubt as to whether a strong wind acting against the side of the car, or the

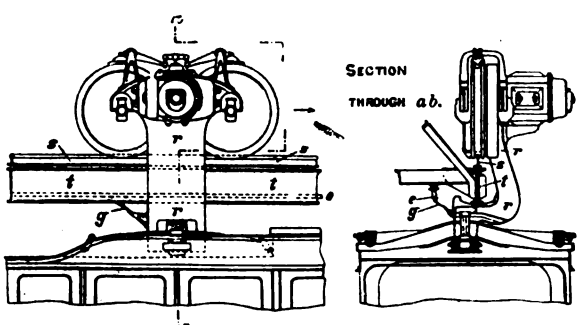

FIG 10.—Suspension of Car.

centrifugal force acting round curves, would not give rise to undue oscillation. To determine this point, exhaustive experiments were made with a car 26ft. in length, but weighing only 2 tons 8cwt. The track, it should be mentioned, allows the car a maximum swing of 15deg. from the vertical. Theoretically this swing would be produced by a continued side pressure of 16½lb. per square foot of surface exposed. The assumption of such a pressure, which would suffice to overturn a tramcar having a length of 39½ft. and a gauge of 3ft. 3in., amply suffices to

Digitized by Google

meet the conditions prevailing in Elberfeld. Some experiments conducted during a violent storm showed that wind pressure is not uniformly maintained. Even when some very sharp gusts occurred, they were not maintained for a sufficient length of time to give the car appreciable side acceleration. The car commenced to swing somewhat in a position slightly out of the vertical, but this inclination was found to be considerably less than that corresponding to the assumed maximum continued wind pressure. As regards railways which are exposed to the full force of the wind only at street crossings, this action of the wind is practically negligible. It was further proved by the experiments that movement of the living load did not result in the slightest displacement of the car; in fact, its weight relative to the weight of the car is too small. As regards the centrifugal force, it need only be

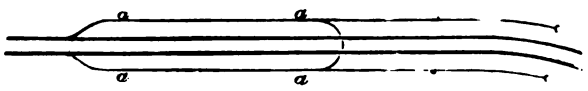

FIG. 11.—Return Arc.

remarked that, generally speaking, the swing of the car might amount to as much as from 30deg. to 40deg. without causing inconvenience to the passengers, so nothing need be feared on this score so far as the Elberfeld line is concerned, since here the swing is limited to about 15deg., as already observed. During the course of the experiments in question curves were negotiated at a speed sufficient to give the car a swing of 25deg. from the vertical, without causing the slightest inconvenience to passengers. It was deduced from the experiments that a car on the suspended railway, which in respect to the inclination of the trains from the vertical is more independent than the ordinary type of railway, may negotiate with safety a given curve at three times the speed holding for an ordinary railway. For the same speed the surface-type railway must be provided with curves of nine times the radius sufficing for the suspended track. A speed of 94 miles per hour would necessitate curves of a radius of not less than 270 yards for the suspended railway, while in order to allow the same speed to be maintained on an ordinary railway, no curve of less than 2,440 yards radius could be permitted. Petersen, a well-known German expert, regards the suspended type of railway as the express transit system of the future.

Although curves of smaller radii may be employed for the suspended railway than for a railway of the ordinary type, on the other hand special care has to be devoted to the shape of the curve in the former case. At the moment in which the car leaves the straight track and enters a curve of a given radius the equilibrium is changed, in consequence of which a pendulum motion is set up round the double angle of the point of equilibrium. Exhaustive experiments with curves of 10 yards radius and upwards led to the conclusion that at least that length of the curve must constitute the transition section as will suffice to allow the car or train to execute a double swing, so that the swing imparted to the car when it has reached the new point of equilibrium may be balanced. If the transition curves are made longer, the pendulum motion is thereby rendered inappreciable. The transition curves must be considerably longer for the suspended railway than for a railway of the ordinary type.

To enable cars to be reversed and transferred to the return track before they have reached either extremity of the line, return arcs (Fig. 11) have been provided at intermediate points, the arc being a curve of 26ft. radius. The loop lines, *a a*, slope from the main tracks sufficiently to allow the electric motors which serve to propel the cars to clear the track above without obstructing the service. When a car is to pass from a siding on to the main track, or *vice versâ*, a sort of climbing switch is employed to raise the wheel flanges clear of the rails. Similar arrangements are provided at the extremities of the line.

At the Vohwinkel terminus a large car depôt has been erected. This depôt contains eight rails (Fig. 12) of which the six outermost ones are connected in pairs by means of loops. Outside the shed the rails are connected by means of the switches, *a b* and *c d*, to a semi-circular track, *a c*, which enables the cars from any rail upon one side of the shed to be conveniently transferred to any rail on the other side. By means of this arrangement and the switches, *e*, *f*, *g*, *h*, the cars are enabled to enter at night into the shed through *f* and *e*, and leave in the morning through *g* and *h*. The cars may be lowered to or raised from the ground level by means of a lift. A cross-section of the shed is shown in Fig. 13, in respect of which it should be mentioned that

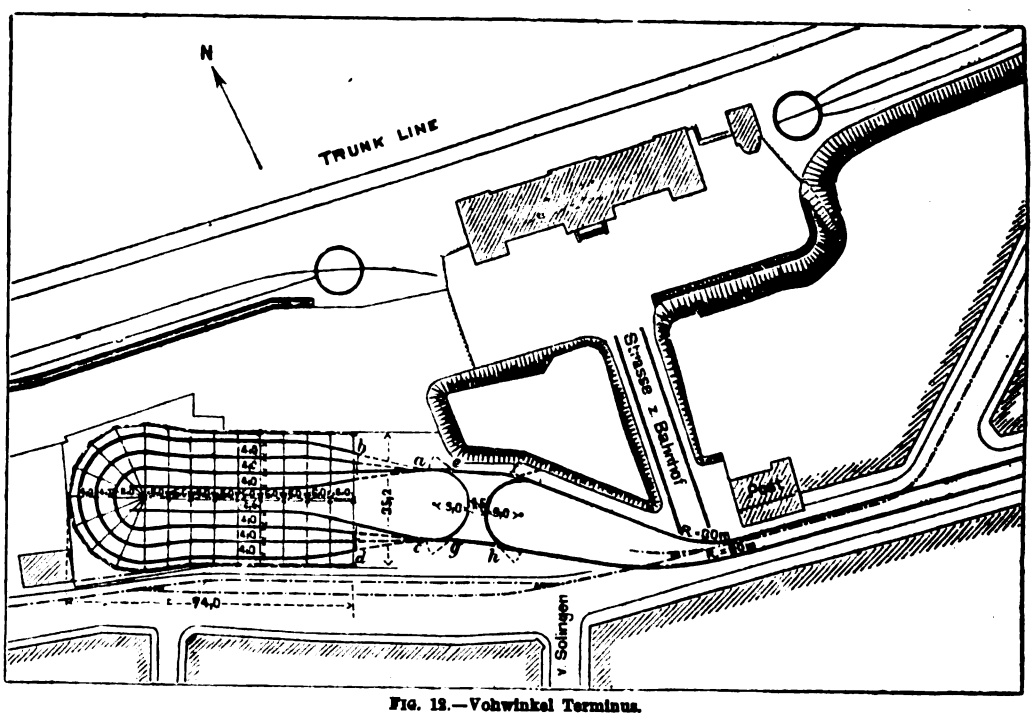

FIG. 12.—Vohwinkel Terminus.

the cars accommodated in the lower storey are street cars belonging to the old electric tramway line. The depôt also embraces repair shops for both services. There is little to be said about the stations *en route*. These are of very simple construction, and have platforms of from 10ft. to 12ft. in width. They are 39ft. to 43ft. broad, and covered in for a length of 82ft., which corresponds to the length of two cars.

Coming now to the electrical equipment of the cars, it must be mentioned that each car is suspended from two bogies (see Figs. 14 and 15), spaced 26ft. apart. Midway between the wheels of each bogie is fixed a 35-h.p. electric motor. This motor is designed to work with an average terminal pressure of 550 volts, and both axles of the bogie are driven by it. The output of the motors may be

Digitized by Google

modified by running them in parallel or series, or by the switching in of resistances in the usual way. The necessary driving current is taken up by the contact shoe, *g* (Fig 10), from the trolley conductor, *e*, which latter consists of an iron rail of light section, and is supported by obliquely-placed insulators. The contact shoe is held by an inclined lever and pressed against the conductor by means of a spiral spring. When several motorcars are coupled together to form a train, the motors belonging to the respective cars are controlled from the driving cab of the front car, which alone in this case collects current from the conductor rail. It may be mentioned here that the conductor rail has a round head, which is embraced by the collector shoe at all positions of the car. The trailer cars are each equipped with a simple controller, motor, and collector shoe, which latter may be let down if necessary, and the car thus rendered self-propelling for shunting purposes, etc. The couplings are at the top of the cars. Great care has been bestowed upon the braking arrangements, several alternative means of braking being provided. A Westinghouse air brake actuated from the driving cab acts from above upon the driving wheels. The same brake mechanism may be actuated by hand both from the driving cab and by the guard. Further, the usual means of electrically braking the car by reversing the current to the motors or by cutting the line current off, and allowing the motors to act as generators, are provided.

The automatic signalling arrangements adopted allow of a two-minute service of cars. At each station are placed signals to indicate whether the line and next station in either direction are clear. The signal indicating the line "clear" is automatically raised to the "stop" position by the rearmost axle of the passing train, while the next signal to the rear is simultaneously placed at "clear" by means of an interlocking arrangement. Should a signal for any reason fail to act when the train is passing it, the next signal to the rear must necessarily remain in the "stop" position, whereby the service is rendered secure. So soon as the driver sees the signal in the "clear" position, he is sure there is no obstruction between his train and the next station. During the journeys between stations he has no signals to bother with, and has only to see that he stops at the next station. A maximum speed of 25 miles per hour is observed for the present. In spite of the frequent stoppages, it has been found that an average speed of 18¾ miles per hour can be maintained. Later on, however, it is intended to increase the maximum speed to 31¼ miles, which will enable an average speed of 22½ miles per hour. With a service of four-car trains the line will be capable of dealing with 6,000 passengers per hour. It may be mentioned, in conclusion, that the current required to work this suspended railway is proved to be very little more per unit of accommodation provided than for ordinary tramways. The manner in which the work has been carried out reflects great credit upon the principal contractors, Messrs. Schuckert and Co.

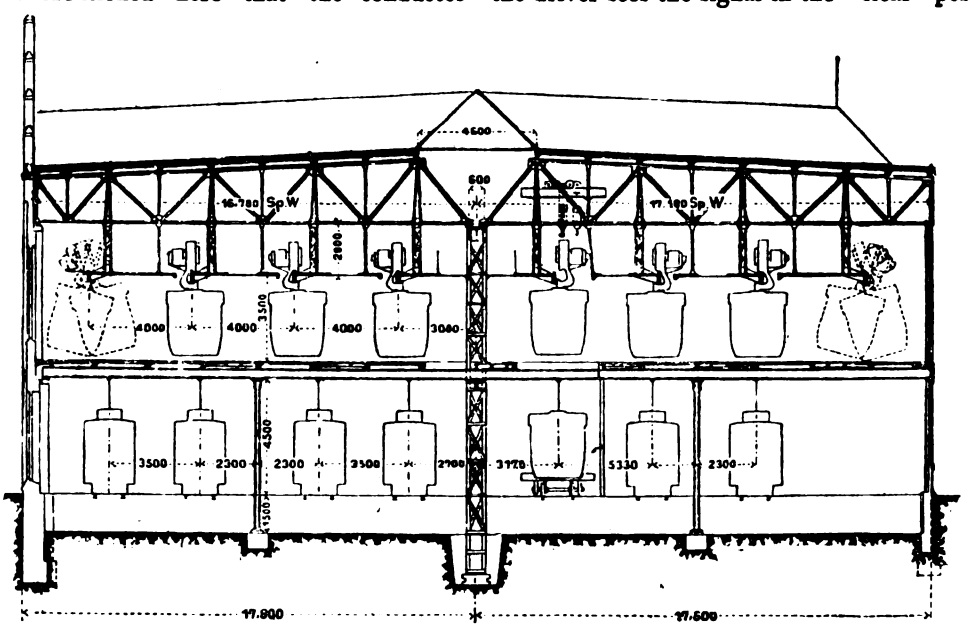

FIG. 13.—Cross-Section of Car Shed, Vohwinkel.

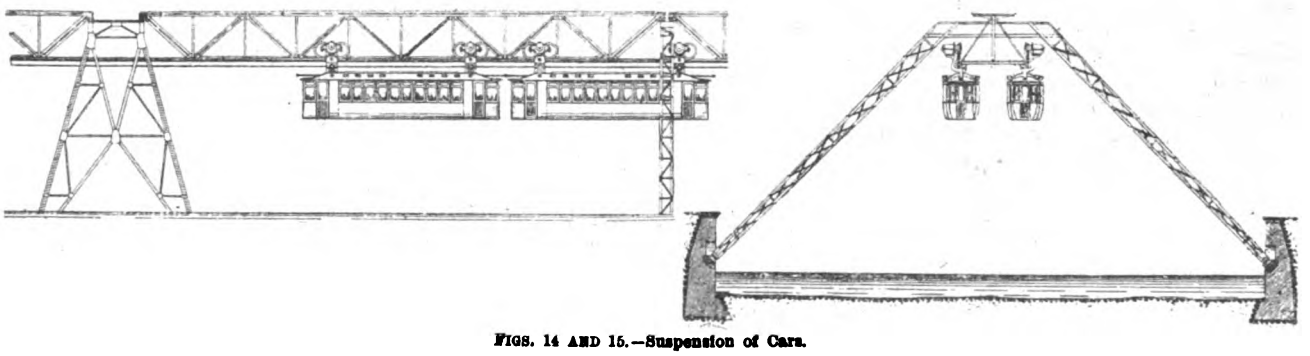

FIGS. 14 AND 15.—Suspension of Cars.

As regards the construction of the car bodies, it may be mentioned that by means of the loop connections already described, the same position of the car relative to the direction of travel is always preserved; that is to say, the driving cab is always in front, so that entrance and exit doors are required only on the right side of the car looking in the direction of travel. These are situated near the ends of the car; they open inwards, and while the car is in motion are kept bolted. Each car is capable of seating 30 passengers, while it provides standing room for a further 20. The cars are run singly at present, but the station arrangements are designed to allow trains consisting of four cars to be run.

THE DEVELOPMENT OF THE DENSITY FACTOR*

BY C TURNBULL, BOROUGH ELECTRICAL ENGINEER, TYNEMOUTH.

The density factor of an electricity works may be defined as the number of 8-c.p. lamps connected per £1 worth of mains laid, or perhaps better as the number of units sold per annum per £1 worth of mains laid. Mains in

* Paper read before the Newcastle Section of the Institution of Electrical Engineers.

Digitized by Google

this case should include transformers and the like. Owing to the great cost of every yard of cable laid, it is of the utmost importance to have a good density factor. Indeed, it may be said, take care of the density factor—*i e*, get the main loaded up with every kind of consumer within reach—and the load factor will take care of itself. The density factors of the following towns, taken quite at random from "Garcke's Manual," will serve to show the great differences that exist:

	8-c.p. lamps connected per £1 worth of mains.	Number of units sold per annum per £1 worth of mains.
Aberdeen	1·21	7·8
Brighton	1·03	25·4
Derby	·89	17·5
Edinburgh	1·12	20·6
Harrow	·64	6·5
Manchester	·94	18·8

The cost of transformers has not been taken into consideration in the above, as it is not shown separately in the manual. Seeing that mains represent some 40 to 50 per cent. of the capital expenditure, I think the figures are worthy of consideration.

Rented Wiring.—To meet those who do not wish to be at the expense of wiring their premises, it has been proposed to take the mains throughout the building instead of stopping at the meter only, and to charge more for the current consumed to cover the extra cost. This method is not entirely satisfactory, especially seeing that the modern tendency is to make consumers pay a fixed sum per annum to cover standing charges, with a comparatively small charge for current used. I would suggest that the following points are desirable in a system of rented wiring: For a plain fitting, including lamp and switch complete, a fixed quarterly rental should be charged. Additional fittings on the same switch should be charged at a second and lower rate. Additional lamps on a fitting not having independent switches should be charged at a third and still lower rate. The hirer should have the option of hire-purchasing the installation at rates based on the rentals, or he should be allowed to purchase outright at any time for a reasonable sum. When the station does the wiring, the rentals, etc., may be settled by an examination of the average costs of installation, but, personally, I prefer to have the wiring done by a wiring firm, as it needs more supervision than most of resident engineers are prepared to give. Besides, with smaller stations at any rate, there will not be a sufficient flow of work to keep an efficient staff busy, unless outside firms were discouraged, which would be foolish. When the wiring is done by contract, the terms must be settled by bargain. In Tynemouth we have arranged with a private firm to do the wiring, we to collect their rentals. A plain fitting costs 5d. per quarter, or a fitting without a separate switch 4d. per quarter; while an additional lamp on a fitting is 3d. per quarter. Double these rates will pay off the cost in 4½ years, or 1½ times the rates will pay it off in 6½ years, or the hirer may buy at any time at a moderate price. Of course these terms are not suitable for large houses, and in many towns special arrangements would have to be made to meet special cases, but it is to be observed that rented wiring is intended mainly for small consumers.

The Two-Meter System.—It has always been a trouble with the maximum demand system that consumers are in fear that their accounts will go up with a jerk if they happen to put on two or three extra lights some night. This has been met in various ways, such as by allowing the demand indicator to be short-circuited on special occasions, or by having two-way switches arranged so that if one lot of lights is switched on, another lot will be switched off. In many cases people will only wire a few rooms in their houses to make sure that they will not at any time be let in for a big bill. It has been proposed to meet the difficulty by having two meters—one to register during the hours of heavy load, and the other during the hours of light load—the units registered on the latter being charged at a lower rate. On examination this will be found unsatisfactory, for a shop which, say, averages two hours a day throughout the year will be charged at the high rate although undoubtedly a good customer, while an office which occasionally overlaps the station maximum demand and takes current only during the winter months will get off at far too light a rate. I would suggest to you that houses which have a good steady load throughout the year will not appreciably increase the station maximum demand by having bedroom and other short-hour lights connected up in addition to their long-hour lamps, nor will they require any heavier mains. It is therefore worth while to do something to rid their occupiers of the fear of a largely increased maximum demand if these occasional lamps are connected up. This can be done by allowing consumers to have two meters, one for the long-hour lights and the other for the remainder. The units registered by each meter are charged as if for a separate consumer, so that practically the full rebate is obtained on the long-hour lights and none on the occasionally used ones. A small extra rent is charged for the second meter, which may generally be of the cheap kind now coming into use. It is also often possible to omit the demand indicator, as, of course, the demand on each meter is the full number of lamps connected thereto This concession has the effect of relieving people from anxiety, so that they wire their houses freely, and I doubt not they will use their light freely too.

THE ELECTRICAL ENGINEERS VOLUNTEERS' WELCOME-HOME FESTIVITIES.

The South African detachment of the Electrical Engigineers (R.E.) Volunteers was entertained to a welcome-home dinner by the other members of the corps at the Trocadero Restaurant, Piccadilly-circus, W., on Saturday night last, Major Erskine presiding. The company numbered about 250 persons, and among those present were Lieut.-Colonel Crompton (the commander of the contingent in South Africa), Captain Lloyd, R.E., Prof. Perry (president of the Institution of Electrical Engineers), Mr. H. Hirst, and Captains Pott, Leaf, Hopkinson, and Baine.

The loyal toasts having been given,

Major ERSKINE proposed the toast of "The South African Detachment." In the course of his remarks, the Chairman read a letter from Lord Kelvin expressing his regret at being unavoidably prevented from presiding at their first welcome-home dinner, and congratulating the men on their safe return from the war. His lordship also sent his best wishes for their health and prosperity. The Chairman, after extending a hearty welcome to the South African detachment, said they would all deeply regret the loss of four of their number from sickness, and also the severe wounds sustained by Lieutenant Stubbs. In reference to sickness, he must congratulate them all on the kindness that both the officers and men showed to their comrades. One man had told him that he believed he owed his recovery to Captain Leaf. The relatives of Sapper Weakley, who died in hospital, had asked that Sapper Cooke should be thanked for his kindness to Sapper Weakley during his illness. He (the chairman) knew they would all join in that sentiment. He hoped that the Royal Engineers who were attached to the active service contingent would carry back with them, when they returned to the regular service, splendid reminiscences of the time they had had with the volunteers at the front, and he thought he might say that the detachment must have gained considerably by having had some of the regulars with them to assist them with their experience in the army.

The toast was enthusiastically received.

Lieut.-Colonel CROMPTON, who was greeted with loud cheers, said he rose to make a speech which to him would be one of the proudest speeches of his life. They, no doubt, expected him not only to return thanks for the kindliness with which they were received there by their own regiment, but also to tell them the story of their life at the front. The circumstances of the war in South Africa were so special, so extraordinary, and the defiance flung down by Mr. Kruger so roused the blood of every Englishman, that it was impossible that they, the scientific arm of the British people, should sit still and do nothing That was why he accepted the honour of being their

Digitized by Google

commandant in South Africa. Those who went to the war tasted for the first time the sweets of soldier comradeship, never to be regretted. Before the detachment started they obtained the services of the very best officer of the regular army that they had met with in the course of their regular training—Captain Lloyd. The presence of this one regular officer proved to be of the very greatest advantage to all of them. The work carried out by the contingent included railway construction—a work which, when the history of this war came to be written, would be set down as the most creditable of the whole campaign. No one would be able to say that the work of reconstructing the railways that was done by Colonel Girouard and his merry men—and the merriest were the Electrical Engineers—did not establish a record in the engineering work of the present century. It was really mechanical engineering carried out in the face of extreme difficulties, and that they were able to do this was due to excellent organisation alone. When passing through the Orange Free State—now the Orange River Colony—the defence of the communications was expedited by this detachment, and this reduced the cost of the war no less than by £10,000,000. Their organisation, their plant, and their equipment were so good that they were able to do work which no other engineers could do. They became railway men and had to do all sorts of hard work, even to carrying sleepers. This continued for about two months, and during that time, although the work was hard, the living bad, and in spite of having to sleep under an open sky with the thermometer 20deg. below freezing point, they managed to struggle up to the Vaal River, and to take their part—and a very large part it was—in the reconstruction scheme. But they were learning to be real soldiers. A man was not a soldier in the full sense of the word until he had tasted the sweets of comradeship. He was sure there was not a man in the detachment who did not feel the better for having seen active service in South Africa. There came a time when the authorities suddenly found out that they could not do without the Electrical Engineers in Pretoria, for it was no secret that they lightened the darkness that existed there, and set the electrical gear to work again. Two months were occupied in real slogging work of that kind, but there were many interesting novelties introduced, and altogether the work was of a very novel nature. He alluded to the different methods of defending the forts by means of light wire entanglements, and these would, no doubt, be copied by the Continental nations before long. Then they went in for a special light type of telephone which enabled them to keep England informed of what took place in the district round which De Wet was operating. Again, there was the work of repairing the telegraph communications, and the danger and risks attending it were very great. These were the services rendered by Captain Baine and Lieutenant O'Shaughnessy, but they never heard a word of them from the newspaper correspondents. Owing to the fact that they were the universal handy men, they had to become gunners as well as engineers—that was, extricating the big 6in. guns out of difficult situations. Their success was such that from that time forward a new duty was found for them. The last words of Lord Roberts to him were that "he considered that the Electrical Engineers had done their duty to an extent utterly unexpected, and that he was extremely cognisant of their value to the army." They had losses from fever never to be sufficiently deplored, but they might congratulate themselves on the fact that so few died, and feel pride in the deeds of those who had passed away. They had left others behind them in South Africa—not to be deplored—those who had secured professional appointments in the country. In conclusion, Lieut.-Colonel Crompton said that if there should happen to be another war, he might say on their behalf that their services would be available, and they had a right to congratulate themselves on the fact that so much of our success in South Africa was due to them.

Captain LLOYD, whose name was also coupled with the toast, said there was one point upon which they might all pride themselves—namely, that, as Colonel Crompton had just said, they had saved the country £10,000,000, and therefore each man was entitled to £160,000. But they had not got it yet, though probably the War Office would eventually, after the proper lapse of time, discharge its obligation to them. He took it to be a very great honour, and one which he would never forget nor under-estimate during his life, to be asked to assist the Electrical Engineers in their work. They had rendered excellent service in keeping the communications open in the troublous times when Lord Roberts was making his famous march to Pretoria. He went forward confidently knowing what he was doing, with the Electrical Engineers in his rear. The detachment then left behind at Bloemfontein had to do very uninteresting work, in lighting the sidings and performing similar jobs, and therefore they had rightly been called "handy men," and for what they had done the army would for ever thank them. Speaking as a regular officer, the men appeared to him to have been under training for years, and he heartily congratulated them upon the efficiency they had displayed.

Prof. PERRY, in proposing the toast of "The Electrical Engineers (R.E.) Volunteers," said he could not speak without preparation, for those lovely impromptus with which he had been credited had taken weeks and weeks of thought; even the printers knew 24 hours before he did that he would have to say something that night. He had suffered a great deal from this war, because for three years before he went to South Africa their colonel had accompanied him on a bicycle ride round Battersea Park every morning, and after he had gone he was compelled to go round the lonely track by himself. He should just like to say that this was the last time they would see Captain Lloyd in his present position, for he would bid them good-bye that night. He (Prof. Perry) happened to be president of the Institution of Electrical Engineers that year, and he must tell them there was not one member who did not congratulate the corps of Electrical Engineers on what had been done by those of the active service contingent in South Africa. Those of them who had stayed at home had obtained a good deal of credit for it, and they were proud of many things they had heard about those who had gone to the war. They had shown great devotion in going out and leaving home comforts, and it was due to the enormous amount of commonsense displayed that they were able to do what was required of them. They were in reality, as had already been said, the handy men in South Africa, and this was a fact that they were most proud of, because they owed their power to the circumstance of their having been trained as electrical engineers. He knew how exceedingly sorry Lord Kelvin was for having been prevented from presiding on that most interesting occasion. His lordship was an oldish man, and his only regret was that he himself was unable to go out to South Africa with the electrical contingent. He (the professor) also felt a large amount of regret that he could not go with them, but their colonel thought that the only thing he was capable of being in the corps was chaplain. He regarded the business of electrical engineers as a very big thing, and there were ample signs that greater things would come of it in the future. It meant that England was going to be able to command the services of professional men like themselves in time of war. In conclusion, the learned professor congratulated them all, and asked them to drink with all cordiality the toast he had had the honour of proposing.

Lieutenant-Colonel CROMPTON, in replying, said if it had not been that the electrical corps had been proposed and organised by the late Dr. Hopkinson up to its present unexampled strength of 400 in three years, there would have been no active service contingent in South Africa, and they should all feel extreme pleasure for the remainder of their lives at having served their country at a time of need. He thought that when this war was over the position England would occupy in the world would be quite different from that she had held before it broke out, and her future prosperity would to a large extent depend upon the advances made by the science of electricity. England had always been a great naval power in the estimation of the world, and who would say that she was not now a great military power as well? The

Digitized by Google

experience gained by the members of the corps abroad would help them now to work out the highest of electrical problems involved in actual warfare.

"The Visitors" was proposed by Captain HOPKINSON and responded to by Mr. HIRST.

An excellent programme of music was provided, a number of artistes kindly volunteering their services. Master Hall sang in fine style "The Lost Chord," while Mr. Will H. Collings supplied the comic element, which was much enjoyed. Miss Esmé Gordon contributed some coon songs, which were warmly applauded. Miss Lily Power and Miss Minnie Pyne sang respectively in character "There is no Dream" and "I'd never Wed a Man like him.' The stirring patriotic song, "When the Boys come Home once more," was rendered by Mr. Scott Russell with striking effect, and Colour-Sergeant-Major Paynton, E.E., gave "Sons of the Motherland" with happy and telling expression. These ladies and gentlemen helped to make up a most interesting and enjoyable programme.

On Monday last the detachment was entertained to another welcome-home dinner at the Prince's Restaurant, under the presidency of Prof. John Perry. The hosts were a number of gentlemen, most of whom had previously combined to give the detachment a send-off dinner at the same place. An excellent dinner was served by the proprietors of Prince's, and a most enjoyable evening was spent both by hosts and guests. Mr. Henry Edmunds, as in the previous dinner, together with Mr. MacMillan, were responsible for the organisation of the evening.

The Reception.

The last of the series of welcome-home functions in honour of the South African detachment of the Electrical Engineer (R.E.) Volunteers was held in the Covent Garden Opera House on Tuesday last, owing to the kindness of Mr. Frank Rendle and Mr. Neil Forsyth. These gentlemen, besides lending the Institution the Opera House, were present themselves, and did all they could to meet the convenience of the large audience. The parquet floor, arranged for fancy dress balls, was in position. This gave a good space for the men of the corps to be drawn up. A guard of honour, consisting of those members of the corps who did not go to South Africa, kept the large central space free until after the formal welcome had been completed. The band of the Royal Engineers played selections of music from eight till nine, during which time the members of the Institution and their lady friends were finding their places. The Council of the Institution, and a number of distinguished military gentlemen, took their stands in the balcony, the platform being occupied by Prof. Perry and Major-General Salmond, R.E. Lieutenant-Colonel Crompton then marched his men in, and they were drawn up in line opposite the guard of honour.

Prof. J. PERRY, in an address of welcome, referred to the inauguration of the corps by Dr. John Hopkinson, who advocated that the professional men of England should train themselves in times of peace so as to serve their country in time of war. The present struggle in South Africa had proved the success of the experiment, and the Institution were proud of the detachment which they now welcomed home. The members of this detachment had not only relinquished, in common with other volunteers, their home comforts, and undertaken the dangers of war, and the still more fatal dangers from disease, but they had also given up positions and chances of promotion in their profession, a sacrifice which the Institution was particularly well able to appreciate. Speaking of those who had died, Prof. Perry said: "We do not mourn as those without hope. Hope that a life laid down by a man for men is not a life thrown away. Hope for a country that can still breed sons who for her sake are not afraid to die." The generals under whom the detachment had served spoke highly of the good work it had rendered, and particularly of the aid the electric light had been in the work of repairing broken bridges, which was able to go on night and day, owing to the exertions of the Electrical Engineers corps. Referring to the general work of the corps, the President said they did any kind of engineering work that had to be done, and showed themselves the handiest of "handy men." Officers and sappers alike took their full share of actual physical toil, but to the civilian members of the Institution the distinction between officers and sappers was merged in the fact that all alike were worthy representatives of the electrical engineering profession. As electrical engineers those present stood higher in their own opinion—and, as he believed, in that of the world—in that the profession had developed in the South African detachment that common-sense, that resourcefulness in time of trouble, that reserved power and moral courage, which had distinguished them particularly in an army of distinguished men.

Major-General SALMOND gave a brief *résumé* of the history of the corps from the time the late Dr. John Hopkinson came to him in 1896. Lord Lansdowne had then at once recognised the importance of the suggestion, which was immediately adopted, in spite of the fact that the estimates for the year were completed. When it was proposed to take a detachment of the corps to the front the Government had done all they could in providing an equipment, and they had also given Lieut.-Colonel Crompton a free hand to provide additional equipment, such as bicycles, etc., out of private funds. He was particularly pleased with the request from the corps that Captain F. L. Lloyd should be sent out in command. He was able to bear testimony to the useful work which the contingent had done in South Africa, and congratulated the regular army on having trained men of their class available in any emergency.

Lieut.-Colonel R. E. CROMPTON, replying for the corps, said how proud he was of the work which the South African detachment had done. He had tried since the lamented death of Dr. John Hopkinson to follow in his footsteps, and had considered it his duty, therefore, to offer the services of the corps when the present war commenced. Their work under Colonel Girouard in repairing the railways had been arduous, but they were pleased to be associated with such an important work. When they got to Pretoria, they found much work to do with which they were thoroughly conversant. Thus they had provided the electric light for various hospitals, and particularly for those on the heights round Pretoria, which proved so successful in fighting the enteric fever. Their work in hauling 10-ton guns up such slopes as 1 in 6 had earned special commendation from the head of the army in South Africa. In conclusion, Lieut.-Colonel Crompton referred to the trophies they had brought home, and presented the captured electric exploder we have referred to before to the President, asking him to add it to the museum of the Institution.

Captain F. L. LLOYD referred to the pleasure it had given him to take out the detachment of the Electrical Engineers Volunteers. They had had hard work to do, and it had been well done by officers and men alike. He thought, however, that due credit should be given to certain electrical engineers whom they had found in the country, and without whose local knowledge they could not have done the good work they did in certain directions. Amongst these was Mr. S. C. Woolley Dod, who stayed at Pretoria during the war looking after the electric lighting installation. When they arrived there, there was no oil to be had and no candles, but with the little coal available and Mr. Dod's mains they were able to provide light to the various camps, stores, and hospitals. Mr. J. Cushing, of Johannesburg, had also done great service in showing them where they could find hidden stores of electrical apparatus which they required in carrying out this work. A third name deserving of mention was Mr. G. M. Clark, of Cape Town, who came to Pretoria to assist in the electrical communications.

After these speeches an exhibition of lantern slides illustrating scenes in the war were shown. Colonel Crompton, in explaining these, was able to give a very good idea of the very varied duties which the detachment had to undertake. It seems that these duties ranged from carrying sleepers for the reconstruction of railway tracks up to defending their lives from attacks from De Wet.

During the rest of the evening the programme was

Digitized by Google

interspersed with selections from the band, while the guests had ample opportunity of conversing with the members of the South African detachment.

A hearty vote of thanks was passed by acclamation to Mr. Frank Rendle and Mr. Neil Forsyth for their kindness in lending the Opera House to the Institution.

The following is a full list of the officers, non-commissioned officers, and men who have returned from South Africa: Lieut.-Colonel R. E. Crompton; Captains F. L. Lloyd, R.E., A. Bain, and H. M. Leaf; Lieutenants A. H. Pott and J. J. F. O'Shaughnessy; Second-Lieutenants H. F. Bigge and F. Powell Williams; Dr. Masters; Sergeant-Major G. A. Brown, R.E.; Sergeant-Instructor C. T. Ruse, R.E.; C.S.M. E. Rorke; Sergeants J. H. S. Phillips, W. S. Entwistle, and A. H. I. Graham; Corporals H. H. Bicker-Caarten, A. Charlton, W. Dalton, and W. H. Hossack; Second-Corporals E. M. Sellon, J. Rook, A. J. Hodgson, and C. Landon; Lance-Corporals H. R. Allen, G. Charlton, S. W. Melsom, D. F. Colson, C. F. Love, M. N. Crawford, A. R. Peart, and A. O. Wiltshire; Sappers F. D. Arundel, H. Bertram, W. C. Cooke, W. G. Carter, A. J. C. Devonshire, R. H. Brander, G. J. H. Elliott, R. W. Holliday, E. C. Horsley, L. H. Hounsfield, A. E. Minns, H. A. Paris, N. W. Pirrie, F. J. Phillips, F. G. Payne, R. B. Roberts, B. H. Tilley, J. D. Taylor, F. J. Wallis, E. J. Wright, and F. J. Young.

The following non-commissioned officers and men are staying in South Africa in the various capacities mentioned: Second-Corporals J. H. Stone and D. G. W. Hume, second-lieutenants Royal Field Artillery; Sergeant T. H. Brown, electrical engineer-in-charge Government Printing Works, Pretoria; Lance Corporal A. E. Levin, private employment; Sapper J. M. Bowrey, employed under the electrical adviser to the Cape Government; Sappers H. R. Claxton and C. W. S. Paine, employed as electricians under the Imperial Military Railways, Pretoria; and Sappers C. E. Silverthorne and F. C. Stephens, private employment. Two men were left behind in hospital—viz., Lieutenant J. H. Stubbs and Lance-Corporal C. H. R. Thorn. The first of these has now just reached England.

The four men who succumbed to enteric fever were: Second-Corporal A. Holdaway, and Sappers E. C. Short, W. C. Weakley, and E. J. West. Their names will stand first on the roll of honour of the corps.

THE GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The above local section of the Institution of Electrical Engineers met in the Institute Buildings, 207, Bath-street, Glasgow, on Wednesday, Dec. 12, at 8 p.m., for the purpose of discussing the paper recently read by Mr. W. E. Langdon (vice-president), to the Institution of Electrical Engineers in London. Lord Kelvin wrote regretting that he was unable to be present, so Prof. MACLEAN, who occupied the chair, opened by giving a short summary of the paper, and then read the following communication which the secretary (Mr. E. G. Tidd) had received from Mr. Langdon.

Dear Sir,—Your section is to do me the honour of discussing my paper on the "Supersession of the Steam by the Electric Locomotive" on the evening of the 12th. I hope it may not be thought that in submitting for the consideration of your president the following observations I am attempting in any way to direct or influence the discussion, but questions having been raised on the occasion of last Thursday's discussion, at the Electrical Engineers in London, of the accuracy of the formula employed by me for obtaining the pounds tractive effort per ton (on which, of course, my calculations are very largely based) I am particularly anxious that this important question should, if opportunity arises, be dealt with. It may be that you may be favoured with the presence of locomotive or mechanical engineers who may be prepared, if the formula which I have used is in their opinion inadequate, to furnish a formula which they may regard as reliable. I may, perhaps, add that I have every confidence in the source from which I received the formula which I have used. I know it to be the result of a number of practical experiments, but I have not yet ascertained that it is applicable to goods trains. The various formulæ given do not attempt to make a distinction between goods and passenger trains. If reference is made to the diagram furnished in Fowler's "Mechanical Engineers' Pocket-Book" for 1900, it will be seen that there are three curves which practically coincide, whilst that of Clark's deviates from these three to a very great extent.

"Molesworth" expresses Clark's as follows:

$$6 + \cdot 009\ V^2.$$

If this is carried out in respect of the No. 1 class of train, shown in my Table IV., it will be found to result in a per train horse-power of 1,045, as against 477 by the formula which I have used; and if it is applied to No. 4 class of train, the demand will be 386 h.p. as against 183 h.p. The difference is, as you will see, very great; indeed, so great as to raise the question whether a steam locomotive travelling at the speed of 50 miles an hour could give that horse-power output.

Another point commented upon was the scheme of plant—whether it was more desirable to employ a central generating station supplying certain sub-stations, or for the sub-sections to be provided for by what I may perhaps call local generating stations. I am clearly of opinion that those who argue in favour of local generating stations have not thoroughly appreciated the many advantages that attach to the central and sub-station system. If each section is to be worked by local generating services, then the machinery established and in operation must be sufficient to meet any demand that may arise on that section, which would mean an increase in cost for plant, coal, and labour. It would be impossible to guarantee a fixed demand. The varying difficulties which arise in working trains at the present time will not be inseparable from trains worked electrically. Practically the same conditions will attend them. The load in the several sections will be continually varying. With a central generating system, the load as it shifts from one section to another will not vary to any great extent the load at the central station; that will remain practically constant, depending upon the *sum total* of the load comprised within the demand of the several sections served by the central station.

Another argument in favour of the central station and sub-section system is that it will be capable of meeting, to a large extent, without stress, the varying demand consequent upon the starting of trains. At the moment when inertia is being overcome in one place there would no doubt be a relaxation of the demand for power at another point—*i.e.*, as an instance in point, a train may be running into a station simply under the influence of momentum without any help whatever from current, whilst at another station a train may be starting, and will require, for a moment of time, a large accession of current. Of course, this would apply to some extent in a local section generating its own current, but it will apply very much more largely with the central-station scheme—that is, as it will take a larger area, so the opportunity for equalisation will be greater.

If after reading this you should think that the matter I have taken the liberty to submit to you is of sufficient importance to read to the members at your meeting, I should feel obliged if you will do so. My great desire, of course, is to get at reliable data. In adopting the formula which forms the basis of my calculations, I placed, as I still do, every confidence in it; but if it can be proved to be wrong to such an extent as to materially modify my deductions, it would be only honest that such should be done. I need hardly, however, add that the matter is one of so great importance that there should be no doubt as to the absolute accuracy and source of any formula that may be advanced in place of that which I have used.—Yours faithfully,

(Signed) W. LANGDON.

P.S.—Since inditing the above, I have received from the author of the formula used by me a communication thereon, copy of which I append. The data was, as you will see, collected from actual experiment in 1891, since which date the tendency due to improved lubrication, etc., should be, if anything, to reduce the tractive effort result.

Midland Railway, Locomotive Department.

W. Langdon, Esq., Derby.

Dear Sir,—I am sorry that I was unable to be present to hear your paper read, and offer some facts in support of the train resistance figures you submitted, for I quite agree with your conclusions on this matter. The formula you have adopted agrees with the results I obtained in 1891 with trains running on the Midland Railway between London and Nottingham. In all about 400 sets of figures were taken, and in calculating the train resistance from them, proper allowance was made for gradient acceleration, energy of revolving wheels, etc. The results agree closely with others obtained by Barbier, Du Bosquet, and other careful investigators. The train resistances at high speeds given by Clark and some others are quite unreasonable. The coal and water consumption of a locomotive is well known, and if such high train resistances were met with we should have to take it that locomotives sometimes

Digitized by Google

run as economically, or even more so, than the best stationary compound condensing steam-engines. Barbier found that the locomotive resistance was greater than that of the train. A comparison of the resistances, I found, for long trains as compared with short trains on the Midland, do not support this view. He also found that four-wheeled coaches offered greater resistance than bogie stock. The figures you have quoted are about midway between those given by Barbier for the two kinds of stock. It must be remembered that on the Midland every care has been taken to use the best possible form of axle bearing for coaches and wagons, and to lubricate the bearings also as perfectly as possible. The locomotive has also been designed, as will be seen upon reference to Mr. Johnson's presidential address, with a view to reduce frictional resistance in every way. It should be borne in mind that even if some steam locomotives offer greater resistance to motion per ton than do the trains they draw, such would not be the case with the electric locomotive, owing to its shape, small size as compared with its weight, evenly distributed load, and absence of all friction except that of the journals. The figures found for passenger trains will, I think, also apply to goods and mineral trains. Should you desire to do so, you may with pleasure make use of this letter.—Yours sincerely,

(Signed) R. M. Deeley.

Mr. Henry Mavor, after some general observations, said that, as Mr. Langdon pointed out, his figures were to some extent hypothetical. Fortunately, however, his figures were not so important as his general conclusions, which were of great value. In Table VII. the generating charges were given at about one-fourth of the total. Looked at from the standpoint of the relative efficiency of a steam and an electric locomotive, and from the fact that the generating plant of an electric power-house gave high electrical and mechanical efficiency, one would expect good results. One must bear in mind, however, that the working results in a generating station supplying a railway demand were far below those obtained on trial with steady load. As an instance, an engine giving 1 i.h.p. for 18lb. steam on trial was found to require nearly 10 times as much on daily running with the variable load obtained in a power-house. He thought it not unfair to estimate the repairs to machinery, motors, etc., from existing data, and in looking over returns of several lines he (Mr. Mavor) found that generally repairs cost from 10 to 20 per cent. of the total expenses; in no case did they reach 30 per cent., as shown in Table VII. He also thought that the advantages of electricity would come out more strongly in the matter of repairs than coal, and expressed the hope that Mr. Langdon's estimate of leakage loss in line at 2½ per cent. would prove excessive.

Mr. Dyson (assistant to Mr. H. F. Parshall) said that Mr. Langdon's general conclusions were of more value than his particular data, and stated that train resistance worked out much higher than Mr. Langdon assumed. He thought that the total efficiency of 58 per cent. taken by Mr. Langdon could be made higher. Of the figures which went to make up this total, the efficiency of static transformers, rotary converters, and ohmic loss might all be increased by 5 per cent. The gearless motor might have an efficiency such as Mr. Langdon had assumed, but it had yet to be proved superior to the single-reduction motor of, say, 78 per cent. efficiency. He suggested a joint committee of electric traction and railway engineers as the best means of solving the problem.

Mr. David Home Morton, M.I.C.E., admired the cheerful optimism with which electrical men faced great problems. The mere fact that they were now discussing trunk-line electric traction before the urban and suburban lines were equipped was proof of their sanguine temperament. Public opinion would, he thought, force railway companies to adopt electric traction on their short-distance lines first, and then data would be available to enable them to judge of its merits on trunk lines. Speaking of results already obtained on the City and South London and Liverpool Overhead lines, both of which were sufficiently long established to warrant deductions being drawn from them, it seemed to be indicated that, in economy at least, the self-propelled car was superior to the locomotive. Notwithstanding this, he questioned if any railway manager would place self-propelled carriages on his line, notwithstanding that they would be much easier on the line. A 45-ton locomotive with, say, four 10-ton coaches, and the average number of passengers, would total up to about 100 tons; this could be taken a mile for 6d., and he had yet to see the electric line which could do that. The boiler of a locomotive was a very efficient steam generator, while the engine was not by any means so inefficient as generally supposed. Moreover, the use of compound engines in a power station was not always justifiable. The power costs of the London and Liverpool lines already mentioned, where compound condensing engines were in use, came out higher than the Glasgow district subway, where simple non-condensing engines were in use.

Prof. Archibald Barr, D.Sc., said that there seemed no immediate prospect of locomotive-building shops being under the necessity of giving up business. The condition most favourable to electric traction was the improved load factor and its influence on economical power generation. In no case could the influence of this improved load factor be better felt than on main lines. The value of levelling up the load could be seen by taking the figures given in Tables II. and III., and plotting the mean as a curve. He also expressed the opinion that electric traction would first be applied to local lines, and afterwards extended to main lines. The smoke problem of large cities would, in a large degree, be solved by the use of electric locomotives in and around large cities, where steam locomotives were responsible for more smoke than at first sight would appear.

Mr. W. W. Lackie also spoke, and in the course of his remarks he pointed out an error in Table VII., where interest was given as ·6901d. per kilowatt-hour. That should be ·0901d.

Mr. B. Field (chief electrical engineer, Glasgow tramways) expressed his total disagreement with Mr. Langdon's figures. First, in his attempt to imitate the traffic on the section of the Midland Railway under consideration he had provided for only half the number of trains actually on the line; second, his choice of an electric system was not necessarily the best; and third, the items which went to make up costs per train mile were open to question. Taking Table IV., it seemed that some of Mr. Langdon's calculations rested on a fallacious basis: the columns headed total mechanical horse-power and kilowatt per train mile being deduced from the number of trains in each class and the corresponding figures for mechanical horse-power per train. This, however, could only give the total kilowatts required to propel all the trains which passed a given point in one hour. Later, the author assumed that there were only 14 trains on the whole 50-mile route. It was clear, however, that with 14 trains at an average speed less than 50 miles per hour, there could not by any means be 14 trains passing a given point in one hour. Further, taking trains of Classes 1, 2, 3, and 4 (Table IV.), run at their respective speeds for 24 hours, there would be between 25 and 30 trains at one time on the 50-mile section—approximately double allowed for in the paper. That would not be of any great consequence if Mr. Langdon had taken the right proportions, but instead of the apportioned trains of each class per hour (third column, Table IV.), there should be: for Class 1, 3 trains; Class 2, 2·85 trains; Class 3, 5 trains; and Class 4, 10 trains. That, the speaker pointed out, threw all the subsequent calculations out. Mr. Langdon had also assumed that because five trains of Class 4 passed a given point in an hour that there were only five trains of that class on the route. That cannot be, unless they run at 50 miles per hour. Proceeding, he expressed the opinion that the tractive effort assumed by Mr. Langdon was inadequate. Regarding Table VII., he pointed out that as each locomotive covered 1,900 miles per week, and the combined wages of driver and assistant would be, say, 80s. per week, the cost would work out to ·5d. per train mile instead of 2·65d. given in the table. With regard to systems, probably three-phase motors on the locomotive would prove best; it would then be possible to have a 15,000-volt transmission line transformed to 1,000 or 2,000 volts, at which pressure the motors would be worked. If that were done, sub-stations, with their moving machinery and attendants, would be replaced by static transformers requiring no attendants. The 10 per cent. loss in rotary converters would be eliminated, while the loss due to conductors

Digitized by Google

would be reduced to about 4 per cent. As a result it might be possible with three-phase motors throughout to improve Mr. Langdon's total efficiency by 20 per cent. Where stops were frequent and speeds always varying, three-phase working could not in the nature of things be efficient; but over long lines, where much of the distance was traversed at constant speed, three-phase working was best. Special slow-speed locomotives could be built for goods traffic and for shunting.

Mr. R. F. YORKE sent a letter to the secretary on the paper, in which he suggested that even if the railway companies would not accept the proposal in its entirety, the Highland railways would benefit by the adoption of auxiliary electric locomotives for working their steep gradients. Where these heavy gradients existed, water power was nearly always present. Take the Highland Railway, for instance, with the steep climb from Struan to the top of the Grampians. The River Garry would furnish any amount of power for auxiliary locomotives. Again, on the West Highland Railway, with the long climb from Spean Bridge up to the summit of the Corrour, the water power of the Spean Valley could provide some 10,000 h.p., which would be greatly in excess of what would be required.

Mr. BARNET, chief engineer, Great North of Scotland Railway, spoke of the disadvantages of the third rail where the line had level crossings, and of the danger to permanent-way employés.

Mr. JOHN L. MACINTOSH, locomotive superintendent, Caledonian Railway, referred to the effects of snow on the lines where a third rail was used.

Mr. PICKERSGILL, locomotive superintendent, Great North of Scotland Railway, pointed out that the influence of excursion traffic had evidently been neglected by Mr. Langdon. In the holiday season from two to three times the number of trains given in Mr. Langdon's table would pass over the line, and the demand, occurring as it did only two or three times in a year, would have to be met by the provision of extra generating plant; thus the load factor would be considerably reduced. He thought Mr. Langdon's figures as to tractive effort were not far wrong. He had made a number of experiments in order to determine the value of that, and his figures came very near to those of Mr. Langdon. A train of 275 tons, such as Mr. Langdon gave in Class 1 (Table IV.) would, according to Mr. Pickersgill's formula, require a tractive effort of 3,300lb., while Mr. Langdon gave 3,575lb. In Class 4 (Table IV.) (goods train) his (Mr. Pickersgill's) formula gave 3,000lb., and Mr. Langdon gave 2,750lb. in his table. Speaking of Mr. Langdon's estimate of £50,000 to cover shunting expenses, he thought that was far too little; bearing in mind the enormous amount of shunting which the Midland Railway had, Mr. Pickersgill thought that the figure might reasonably be multiplied by 4.

At the close of the discussion Mr. H. A. MAVOR moved that the meeting send a hearty welcome to the corps of Electrical Engineers on their return from active service. Some would no doubt be present at the reception in London on Tuesday, but those who could not would, he felt sure, be glad of an opportunity of expressing their appreciation of their electric soldiers.

Mr. WM. MACWHIRTER, as a member of the corps—not at the front—and the oldest member of the Institution in Glasgow, expressed the pleasure which it gave him to second Mr. Mavor's motion, which was carried with patriotic enthusiasm.

OPENING OF STOCKTON ELECTRICITY WORKS.

A distinct step of progression in the history of the ancient borough of Stockton-on-Tees was made on Tuesday of this week, when Alderman Richard Hind (ex-master of the Worshipful Company of Plumbers, and chairman of the Gas and Electricity Committee of the Corporation) formally opened new electric lighting works in that town. At 3.30 in the afternoon he received a large number of guests at the works, which adjoin the Corporation gasworks. These included the Mayor and Mayoress of Stockton (Councillor and Mrs. Crosby), several other members of the Corporation and their wives, the Mayor and Mayoress of Thornaby (Alderman and Mrs. Crossthwaite), Mr. Thompson (representing the Brush Electrical Engineering Company), Mr. C. S. Vesey Brown (electrical expert and adviser to the Corporation), and many others. Through illness the manager of the works (Mr. W. Ford) was unable to be pretent.

Refreshments having been served, and an inspection of the works made, the MAYOR took the chair and opened the formal proceedings. He expressed regret at Mr. Ford's unavoidable absence, and said he hoped that the electric works would prove as profitable to the ratepayers of the town as had the Corporation's gasworks.

Alderman R. Hind then started one of the engines, after which Mr. THOMPSON, on behalf of the Brush Company, presented him with a bronze standard lamp as a memento of the event.

Alderman HIND returned thanks, and then his youngest daughter presented a handsome bouquet of flowers and silver stand to the Mayoress, who turned on the first lights, which were a signal to illuminate the station and town electric lamps.

A number of speeches followed giving the history of the scheme up to date, from which we gather that Mr. Ford prepared the plans for the buildings, and Mr. C. S. Vesey Brown, of Lincoln, the plans and specifications for the electrical section of the work; he also acted as expert adviser and inspector. Mr. Ford then became the general manager of the whole works. The tender of the Brush Electrical Engineering Company, Limited, of London and Loughborough, was accepted for the electrical installation complete. Application was made to the Local Government Board for power to borrow £26,500, the estimated cost of the scheme, after which the work was proceeded with. Demand has already been received from 75 consumers for lights equal to 5,700 8-c.p. lamps, in addition to the street lamps, and it is expected this demand will be increased when the mains are laid in January next in Yarm-lane, Oxbridge-lane, and to West Villas.

Mr. C. S. VESEY BROWN then gave a technical explanation of the scheme, and informed the company that the engines were not of the same pattern as those used by the local tramway company, but still, if at any time anything went wrong with the tramway company's engines, the Corporation's engines could be used to supply the motive power for the tramways.

Alderman J. RICHARDSON (ex-member for South-East Durham), in moving a vote of thanks to Alderman Hind, observed that the gasworks during the 30 years they had been in their possession had been a source of profit to the town to the extent of £5,000 a year. He trusted that the electric works would turn out as profitable a concern.

Alderman J. SAMUEL (ex-member for Stockton) seconded, and spoke of Alderman Hind, who had for the past 10 years taken a deep interest in the electric lighting scheme of the town, and who, as a matter of fact, took a very deep interest in everything appertaining to the welfare of the municipality.

Alderman HIND replied, and moved a vote of sympathy with Mr. W. Ford.

The TOWN CLERK (Mr. M. B. Dodds) seconded, and it was carried.

On the motion of Councillor T. B. WATSON, seconded by Councillor GREEN, a vote of thanks was accorded the Mayor and Mayoress; and after a reply from his Worship the interesting proceedings terminated.

FORTHCOMING EVENTS.

FRIDAY, DEC. 21.

Institution of Civil Engineers.—At 8 p.m., students' meeting, Prof. Alex. B. W. Kennedy, F.R.S., in the chair. Paper on "The Use of Geometrical Methods in Investigating Mechanical Problems," by Mr. C. E. Inglis.

THURSDAY, DEC. 27.

Royal Institution of Great Britain.—At 3 p.m., lecture on "The Sun and its Heat," by Sir Robert Ball.

SATURDAY, DEC. 29.

Royal Institution of Great Britain.—At 3 p.m., lecture on "The Earth and its Heat," by Sir Robert Ball.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street London, E C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

SCIENCE AND PRACTICE.

It is generally considered by devotees of pure science that they lose caste if they attempt to deduce practical applications from their scientific researches. It is claimed by such that the pursuit of science has its own reward, and that it should not be debased by any considerations such as the financial gains from commercial applications of the discoveries made. In spite of this, we are repeatedly assured by certain scientific men that the laboratory experiment of to-day is very frequently the workshop practice of to-morrow. In fact, we are assured that in electrical engineering this is almost always the case, and we are therefore warned that we must not allow our practical work as electrical engineers to interfere with standard laboratories. While not concurring with the conclusions to be drawn from the last statements, which premise extreme commercial value to the deductions from observations on terrestrial magnetism, we admit fully the first part of the statement. As a practical example, we would give the remarkably successful work carried on by Mr. W. Duddell at the Central Technical College. The paper read by this gentleman before the Institution of Electrical Engineers last week on the "Rapid Variations in the Current through the Direct-Current Arc," is a remarkable combination of scientific research with practical applications of that research to everyday practice. We have not space here to refer in detail to the various interesting discoveries first published in this paper, and which are so carefully explained by the author. It is worthy of note, however, that in every case he is not content with giving the physical phenomena he has observed, but has traced down the causes of these phenomena by means of other scientific experiments and deductions. As an instance of this, we would refer to the experiments shown by the author on the extinction of a direct-current arc by connecting across the electrodes a condenser. This primary fact was so thoroughly investigated by Mr. Duddell that he was able to give to the meeting information as to the extremely small interval which must elapse between the extinction of the arc and the re-establishment of a high resistance between the electrodes. Thus, if the arc takes place between carbon electrodes, it can be interrupted for an appreciable time and then re-established by again applying an E.M.F. With the arc between metallic points, however, Mr. Duddell clearly shows that if the current is interrupted for so short a time as a twenty-seven thousandth of a second, it cannot be relighted by the application of from three to four times the normal voltage required to maintain it. Another interesting observation made by the author was that on the interruption of an arc between metallic electrodes due to a condenser being connected across it, the voltage rose to an exceedingly high value. For instance, with an arc taking three amperes at about thirty volts, the rise of pressure when a condenser is shunted across the arc was quite sufficient to rupture a sheet of paper which took about a thousand volts to pierce. This rise is increased

Digitized by Google

by having an inductive resistance in series with the arc. Having ascertained this fact, the author was able to apply it to the perfection of the common induction coil. In this, instead of leaving the condenser always connected to the two sides of the contact breaker, he arranged a commutator which only connected the condenser to the contacts immediately after the circuit had been broken, and while the small spark between the contacts still persisted. By this means the length of spark was increased very largely. The increase of length of spark on the coil exhibited at the Institution was quite three times the length of the spark when the condenser was used in the ordinary way. This application of a commutator with an induction coil to inject the condenser into circuit at the right instant is one which alone would have been worth all the time devoted to the subject by Mr. Duddell. An application, however, which will be of much more interest to the electrical engineer who devotes his time to heavier work, is the application of Mr. Duddell's discovery to ordinary switch contacts. It has been the aim for years to design switch gear which shall give an extremely rapid break in order that destructive arcing may not take place at the contacts. It is now clear from the experiments that when such switch gears have to be used in connection with the underground cables, the quick break may be absolutely harmful, as it may result in a rise of voltage which may pierce the insulation. Mr. Duddell has shown that with certain proportions of self-induction and capacity, the rise of voltage at the instant after the break in the circuit may amount to over thirty times the normal voltage of the circuit. From this it will be seen that if the primary voltage were one thousand, a most destructive E.M.F. might be caused. It will be a consolation, however, to practical engineers to learn that by using carbon breaks with their switches these ill-effects are practically avoided. There were many beautiful experiments shown by Mr. Duddell at the Institution, a description of which will be found in our columns, and it only remains for us to congratulate the author on the success of his investigations from both a practical and scientific standpoint.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STEAM ALTERNATOR TEST.

SIR,—I have pleasure in giving herewith the results of a steam consumption test made on a 300-kw. steam alternator supplied recently by Messrs. Ferranti, of Hollinwood, to the order of the Cardiff Corporation. The figures are sufficiently good to interest, I believe, several of your readers, and the names of the gentlemen who conducted the tests are a guarantee of their reliability and accuracy. The plant comprises a vertical compound condensing engine having cylinders 18in. and 34in. by 18in., with an alternator of Ferranti's well-known copper armature type between the high-pressure and low-pressure engines, the whole designed to give 300 kw., 2,500 volts and 120 amperes, 40 periodicity, and 200 revolutions per minute. The valves are of the gridiron type, driven by cam gear, the governing being effected by a throttle valve, and there is forced lubrication. The alternator drives its own exciter.

The test was made on Nov. 8, 1899, there being present, as experts on behalf of Messrs. Ferranti, Mr. M. Longridge, Mr. A. B. Mountain, and Mr. Gillert; on behalf of the Cardiff Corporation there were Mr. H. R. J. Burstall and Mr. Llewelyn B. Atkinson. The test was started at 9.15 a.m., and continued at full power until 4.12 p.m. The steam from the engine was discharged into a surface condenser, which only received the steam of this engine. The air-pump discharge was measured by being run into two barrels, one being filled while the other was being emptied, each being filled up to a mark. During the trial 69 pairs of barrels were used, making a total of 53,030lb. The next day a test was made to ascertain whether the condenser was tight, and it was found a leak equal to 1 per cent. existed, making the total water used equal 52,500lb. It was found that 92lb. of water had collected in the drain sump under the engine, having escaped from the glands, which has to be added, making a final total of 52,592lb. The duration of the trial being 6·95 hours, the quantity of steam used by the engine was 7,568lb. per hour. The vacuum as measured in the exhaust pipe close to the engine was 18·7in., or 9·2lb. per square inch. The alternator was run on a water resistance, the power was measured by a number of ammeters and voltmeters, one of each being chosen after comparison with a Kelvin watt balance as being the most accurate, and readings were taken every 15 minutes. There was also a Thompson recording voltmeter, which was read every 30 minutes.

Each of the instruments read during the trial were sent to the Board of Trade laboratory immediately after the trial for calibration, and the necessary corrections have been made in the calculations. The mean output of the alternator was 315 kw. The mean horse-power shown by the indicator cards was 499 at the mean speed of 204·9 revolutions per minute as got from the engine counter. The combined efficiency of the engine and alternator, taking the above figures for electrical output and indicated horse-power, was 84·6 per cent.

Taking the figures actually obtained, the steam per kilowatt-hour was 24·03lb, being practically 2lb. below that required by the specification. I think this is very good, and if the vacuum had been 26 or 27, the result would, of course, have been materially better. No special preparations were made to prepare the engine for this test. The steam was not superheated, and supplied from boilers of the dry-back marine type.—Yours, etc.,

N. APPELBEE, Electrical Engineer.

Cardiff, Dec. 11, 1900

MUNICIPAL TRADING.

SIR,—May I draw your attention to the following extract from a judgment given recently by Mr. Justice Bigham in a case claiming a declaration that the chairman of a certain urban district council was disqualified from sitting as a member of the council, on the ground that he was concerned in a bargain or contract entered into with the council, and participated in the profit derived therefrom:

"Bigham (J.) said he was of opinion that the defendant was concerned in the contract, and that, therefore, he was disqualified from remaining a member of the council. His experience showed him that there were on these local bodies too many men—builders, and men of that class—who were liable to become, and did become, interested in the work which the councils had to carry out. Such persons, in his opinion, ought not to be elected on such bodies at all, because they were tempted by their own interests to undertake contracts and to enter into dealings with which they ought to have nothing to do."

That this is not an isolated case would appear from the following extract from the *Daily Express*:

"Manchester.—Town Councillor Resigns.—Councillor Rigson yesterday resigned his position on the Salford Town Council in consequence of allegations made against him of carrying out contracts for the Corporation. He admitted having done sub-contracting work, and said he had no ulterior motive. The Mayor did not think there was

Digitized by Google

any council in England some member of which was not interested in a corporation contract."

Again, in consequence of another complaint, the Manchester Town Council have laid down the principle that a member of the Council is prohibited from trading, directly or indirectly, with the Council or any of its committees; and this would seem right, as the members of these councils are trustees for the ratepayers.

I have pointed out in a previous letter that the outstanding loans of local authorities have increased by 150 per cent. in the last 20 years, and they now stand, according to the Local Government Board's report, at £252,135,174.

Local authorities generally throughout the country are embarking more and more in trading undertakings, necessitating contracts for the supply of goods and materials to an enormous extent.

In the result it would seem that either :

1. Municipal trading must be stopped ; or,

2. These trustees must be allowed to be personally interested in the contracts they enter into on behalf of those for whom they are trustees.

Is the latter desirable in the public interest ?—Yours, etc.,

KENRIC B. MURRAY,
Secretary, Municipal Trading Committee.

Botolph House, Eastcheap, E.C., Dec. 19, 1900.

REVIEWS.

The Life Story of the late Sir Charles Tilston Bright, with which is incorporated the Story of the Atlantic Cables and the First Telegraph to India and the Colonies. By his brother EDWARD BRAILSFORD BRIGHT and his son CHARLES BRIGHT, F.R.S.E. Two vols. Archibald Constable and Co.

These volumes we intended to use as a text for a monograph, but for many reasons that has been found impossible, and we must content ourselves for the present with a short and incomplete notice of the many matters treated therein. We must content ourselves with a bald uncritical narrative, in that a number of controversial matters are raised in the text, to fully examine any one of which would need a volume. It may be held that a brother and a son would, in writing the biography of a brother and a father, be somewhat biassed in his favour. This is as it should be, and we commend them for it, yet in future years the strict historian will probably place other men upon an equal pedestal to him whose life's work is recounted in these pages. Sir C. T. Bright was amongst the pioneers in cable work, and especially in Atlantic cable work. We have always held that owing to the rapid progress in telegraphy the world has never really understood the great temerity, perseverance, and plunge into the unknown made by these pioneers. To carry out their projects, the value of which, if successful, was but faintly understood, needed not only the conviction of scientific men as to the possibility, but the far more difficult task of converting moneyed men to finding the capital in return for promised dividends. It is easy to talk now when the work is accomplished, but the difficulties in the way of those who proposed Atlantic cables in the early fifties can hardly be understood. Sir C. T. Bright was one of the band who fought the fight and who lived to taste success. As his biographers say, the part he played "in this then unprecedented enterprise included the scientific demonstration of its practicability, the projection, the provision of capital, and the ultimate successful laying of 2,200 miles of cable across ocean depths of two or three miles. . . ." The great interest of these volumes centres around the history of the work in connection with the first Atlantic cables, and in a minor degree to that in connection with other cables laid east and west in the years following the successful laying across the Atlantic. Thus the early history of the brother, the position of telegraphy given in the pages prior to the section (p. 109) concerning the "formation of the company and construction of the cable," though immensely interesting to relatives and personal friends, are not so to the ordinary reader. Those who carefully read the section just referred to will form some ideas of the difficulties overcome. Can we imagine America, the land of the masterful, the go-ahead and the speculative, subscribing for only 27 shares, or less than one-twelfth of the total capital. Evidently there was not much faith in the venture, but these pioneers persevered and ultimately succeeded. The specification of the cable was hardly so definite as one would be now, and was not altogether in accord with the views of the engineer, nor those of Prof. Thomson (now Lord Kelvin). But we cannot enter into details. The rest of vol. i. reads like a chapter in a novel, wherein for a time the villain carries everything before him, till towards the end come the ringing of the bells to the shouts of victory, while all that troubled is at rest in that bourne from whence there is no return. Bright received recognition from his country for his services. The exact position he holds in the history of the work is hardly to be determined, but whatever that position, his claims and his work are described with great skill by his biographers. The second volume of these memoirs is less interesting. It describes work of various kinds, most of which was rendered easy by the experience gained in the Atlantic. It shows, moreover, that Sir C. Bright was an indefatigable worker—that he interested himself in business matters altogether wide of electricity.

ELECTRIC OSCILLATIONS.

The fourth and last Cantor lecture on this subject was delivered by Prof J. A. Fleming at the Society of Arts on Monday last. The lecturer stated that, whereas previously he had gone into the question as to how electric waves could be produced and the medium through which they could be transmitted, he proposed in the present lecture to look into the question of what the waves resembled and the properties by which they were rendered apparent. He gave the following list of types of waves and the resistance against which each was exerted in the propagation of the waves in question :

Type.	Resistance to
Gravitational waves	Change of level
Capillary waves	Increase of surface
Compressional waves	Change of volume
Distortional waves	Change of shape
Electric waves.....	Electric displacement

As a rule, in order to set up any kind of wave a sudden movement was required, which would cause the energy to leave the wave-forming body and to travel through space. He would warn his audience that the term "electric displacement" had not yet been thoroughly defined. Even Maxwell, who introduced the expression, did not see his way to explain in a few words what he considered electric displacement to be. Dr. Fleming then proceeded to describe Hertz's historical experiments by which he found evidence of the existence of these electric waves. He repeated to a very large extent the original experiments of Hertz, dealing first with the Hertz oscillator connected up to the high-tension terminals of an induction coil, and with the Hertz resonator, which consisted of a circle of wire with a small air-gap of about a millimetre in it. It was experimentally shown that when this resonator was touched against one of the plates of the oscillator, a spark passed between the balls unless the point of contact was diametrically opposite the spark-gap. In view of the fact that 1,000 volts are required to make the spark pass over the gap, electrical engineers would not have predicted that the discharge would have occurred, in spite of the fact that the copper wire connecting the balls was only 1½ yards long. The reason why this occurred was that the oscillations were too rapid to allow the discharge to get round the wire, as the frequency used was about 150 millions per second. Hertz then tried isolating the resonator from the oscillator, and found that in certain conditions he still got sparks. In fact, as long as the spark gap in the resonator was parallel to the axis of the resonator the sparks passed, but if the resonator was moved round so that this spark-gap was at right angles to the axis of the oscillator, there was no discharge. In order to make

Digitized by Google

this experiment clear to the audience, Dr. Fleming introduced a condenser into the resonator circuit, as illustrated in the diagram. A gold-leaf electroscope was connected to one side, and the resonator was then charged up. When the spark caused by the electric waves passed the air-gap, this gold-leaf electrometer was discharged, affording an indication of the fact. The next experiment made by Hertz was the effect of a large zinc plate behind the resonator, and he showed that certain positions of the zinc plate behind the resonator stopped the sparking, while in other positions it still continued.

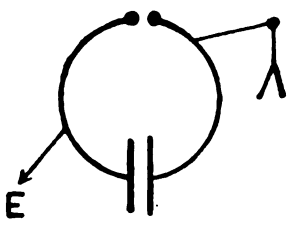

FIG. 1.

The first idea was that the oscillator sent out waves, and that by means of the zinc plate the position of the nodes and loops in these waves had been discovered. It was shown afterwards, however, by Messrs. Sarasin and De la Rive that the distances between the zinc plate and the resonator when sparking took place were functions of the size of the resonator. The lecturer explained that this was due to the fact that the oscillator used by Hertz was in such a form as to send out exceedingly few oscillations. In fact, the waves so rapidly died away that it was doubtful if more than one complete wave occurred. The Hertz resonator, on the other hand, was an exceedingly good oscillator, and hence had a very distinct period. What then occurred was that the oscillator caused one big displacement in the resonator circuit, which died away in a number of waves, and the wave-length was indicated by the position of the zinc plate. When the zinc plate was at a quarter wave-length from the oscillator it helped in the production of these waves, whereas if it were at a half-wave distance it stopped it. The Hertz experiments required great space in which to conduct them, but Dr. Fleming had designed and he exhibited at the lecture a most interesting apparatus by which the whole of the Hertz effects could be shown on a lecture table. As an indicator of the presence of these waves he used a Branly radio-conductor, or, as it is commonly called, a coherer. The two discharge balls of the oscillator were enclosed in a

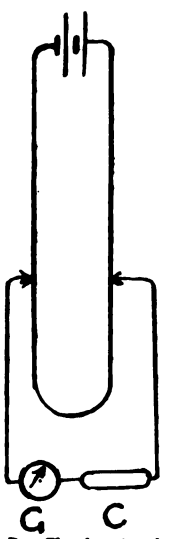

FIG. 2.—Apparatus used by Dr. Fleming to show that a coherer suddenly became conductive as the E.M.F. applied increased.

zinc box with a rectangular opening, so that the electric waves were sent out in one direction only. The conductors to the balls were encased in ebonite tubes, in which spirals of copper wire were coiled to prevent these wires sending out radiations. The radio-conductor was also encased in a zinc box with an opening so as to allow waves to enter from one direction only. The lecturer explained that it was most important there should be no unsoldered joints in this box through which the waves would enter. The connections between the radio-conductor and the relay were also encased and surrounded by a choking coil to prevent the waves acting on anything but the radio-conductors. When these two pieces of apparatus were placed with the openings opposite each other, the discharge from the oscillator sent electric waves which influenced the resistance of the radio-conductor, causing the relay to act and the bell to ring. It was then shown, by inserting a number of substances in the space between the two openings, that all metals stopped the waves, whereas other substances, such as paraffin, wood, cloth, etc., were transparent to the waves. Anything which contained water stopped the waves, but ice when dried did not. From these experiments it was then shown that those substances which have true dielectric constant, and obey Maxwell's law, were transparent to the waves. In the case of water the dielectric constant was 80, whereas the square of the refractive index was about 2. Experiments in reflection and refraction were also shown very conveniently by the apparatus in question. It was explained that the reason why wireless telegraphy was much more successful over sea than over land, was because the land would absorb the waves, whereas they were reflected from the surface of the water. The extreme dryness of the land in South Africa was in a large measure responsible for the want of success which wireless telegraphy had experienced in connection with the military operations in that country. A long chart of wave-lengths was exhibited by the lecturer and a special reference made to the great span in the middle of the scale, waves corresponding to which have not been discovered and investigated. As regards the books he would recommend students to read on the subject, the original memoirs of Hertz translated by Prof. Jones stood first. The treatises by Prof. J. J. Thomson should also be obtained, while Dr. Larmor's work on etheric theory was worthy of careful study. He concluded by thanking the audience for the great attention they had given his lectures, which it had been a pleasure to prepare.

Sir FREDERICK BRAMWELL then proposed a vote of thanks to Dr. J. A. Fleming for his most interesting series of lectures. He knew of no man who was able like the author to make intelligible such intricate subjects. The lectures delivered by him had the advantage that one not only thought one understood the lecture while it was being delivered, but actually was able to make it intelligible to others after the course was over.

Dr. FLEMING briefly replied to the vote of thanks.

LONDON COUNTY COUNCIL TRAMWAYS.

At Tuesday's meeting of the London County Council the Highways Committee brought two important matters before the Council. The first was an agreement with Dr. A. B. W. Kennedy with respect to his remuneration for the construction of the three sections of tramways between Westminster Bridge and Tooting, Kennington-gate and Blackfriars Bridge, and St. George's-circus and Waterloo-road. This new agreement had to be made in consequence of variations from the old agreement of Oct. 10, 1899, due to the fact that certain of the lines then mentioned cannot at present be constructed owing to the failure of the Council to get the requisite powers. The other matter which came before the meeting was that of the appointment of an electrical engineer in connection with the tramways department. In view of the large amount of work which has to be done in the construction of certain new tramways and the reconstruction of old lines for electric working, the Highways Committee rightly think that they should have an expert of their own, who would be the better able to supervise the running and maintenance of the system because he had been with the Council during the whole time that the works were going on. It will be remembered that the total length of the tramways which are to be constructed or reconstructed is about 100 miles. The salary suggested by the committee is £1,000 a year, and the gentleman selected would go in the chief engineer's department, holding a position analogous to that occupied by the mechanical engineer. A resolution to this effect was carried.

ON RAPID VARIATIONS IN THE CURRENT THROUGH THE DIRECT-CURRENT ARC.*

BY W. DUDDELL, WH.SC., ASSOCIATE.

It may be thought by some that the title of this paper is rather contradictory, in that there should not be any variation in the current through a direct-current arc. I will therefore explain at once that I simply use the term "direct current" as implying that the current is supplied by cells or by a direct-current dynamo, and not as implying that the current is necessarily constant in value. It may also be as well to state that by "arc" I do not mean arc lamp, as all the effects to be described are quite apart from those produced by regulating mechanisms. The effect of varying the current through the direct-current arc very slowly, so slowly, in fact, that the carbons have time to burn into shape corresponding to each value of the current, has been investigated by many experimenters, but it is to Mrs. Ayrton that the honour belongs of giving a complete investigation of all that occurs when any of the variables in the direct-current arc are changed in any way. The other extreme—namely, very sudden changes in the current—has also been investigated by Mrs. Ayrton, thus leaving a gap in the experimental evidence as to what occurs between very slow variations and isolated sudden changes in the current.

The present paper is an attempt partly to fill this gap by giving an account of what occurs when the current is periodically varied more or less rapidly over a range which is very small compared with the mean value of the direct current. The current through a direct-current arc supplied with power from any circuit may vary either owing to changes taking place in the circuit—such as variations in E.M.F. or resistance, or owing to effects in the arc itself, such as hissing, humming. Although any variation in the current naturally entails a corresponding change in the arc itself, it will, I think, be found convenient to classify the observed effects according to whether the primary cause of the variation is in the arc or in the circuit which supplies it.

PART I.—CAUSE OF THE VARIATION OF THE CURRENT IN THE CIRCUIT SUPPLYING THE ARC.

The effects of varying the current may be divided under four heads—viz., the effect on the P.D. between the terminals of the arc, on the light emitted, on the shape of the craters, and on the vapour column. These will be considered in order. I shall assume in all cases in Part I. that the amplitude of variation of the current from the mean is small, generally much less than 10 per cent., and that the arc experimented on is neither hissing nor humming.

Effect on the Potential Difference Produced by Variations of the Current.—If the current varies very slowly, then the relation between the P.D., current, and length is that given by Mrs. Ayrton's curves. Directly the rate of variation is increased so that the carbons have not time to burn into shape, corresponding with the instantaneous values of the current, the relation will be changed, and it is conceivable that if the rate of variation were high enough and the amplitude small enough the conditions of the arc would in no way be changed, so that the ratio of the change in P.D. to the corresponding change in current would be a constant and equal to the true resistance of the arc. I shall show later that this assumption, which is the basis of several experiments on the resistance of the arc, notably those by Messrs. Frith and Rodgers, requires a much higher rate of variation of current than they employed. One of Mrs. Ayrton's curves, contained in a letter by Prof. Ayrton to the *Electrician*, illustrates very well how the connection between the P.D. and current depends on the rate of variation of the latter. This curve shows that the first effect of suddenly increasing the current through a cored-solid arc† is to cause a transient rise in the P.D. between the terminals; the effect of a slow increase of current being, as is well known, to produce a decrease in the P.D. This first transient rise in the P.D. which was obtained with a cored-solid arc was also, I believe, obtained with a cored arc, but I am unaware of its having been observed for a solid arc. Thinking that this might be due, as pointed out by Prof. Ayrton, to the extreme quickness of the phenomenon when both carbons were solid, I tried to record the transient rise in P.D. for the solid arc by means of an oscillograph, the sudden increase of the current being obtained by discharging a condenser through the arc. This experiment was successful, and a transient rise in P.D. was observed, the P.D. and current increasing together, but only for about 1/5000 second. At the end of this very short time the P.D. decreased with an increase of current in the ordinary way. If it can be assumed that during this first 1/5000 second the conditions of the arc are not changed, then the solid arc has a positive resistance, contrary to the results obtained by Messrs. Frith and Rodgers, and it is at any rate evident that, had the frequency of their superimposed alternating current been 5,000 ∼ per second instead of 250 ∼ per second, the sign of the resistance as obtained by them would have changed, though I do not say that even at that frequency its true value would have been obtained. In any method for measuring the resistance of the solid arc which depends on the change in the P.D. produced by a change of current, these changes must, therefore, take place in less than 1/5000 second in order not to allow the arc conditions to change; results to be described later indicate a still shorter time. I will not, however, pursue this subject any further, as it would unduly extend the length of this paper to include a description of a complete series of experiments on the resistance of the arc which I have recently completed.

Effect on the Light Emitted Produced by Variations of the Current.—It is well known that the light of the arc varies when the current is changed, though how small and rapid the variation in current may be and yet produce a perceptible change in the light does not seem to have been investigated. Prof. Fleming and Mr. Petavel and Mr. Burnie have determined the instantaneous values of the light and current in the case of alternate-current arcs, and have found that the variation in light roughly follows the variation of the current; the maximum luminous intensity occurring about 1/1000 second later than the maximum current. Herr Görges has also noticed that the variations in the current due to the teeth on the armature of a dynamo produced an appreciable variation in the light at the rate of 300 per second. In order to test how rapid and how small a variation of the current from the mean could be detected in the light of the direct-current arc, I arranged an arc so that its image as seen through a central slit parallel to the carbons was projected on to a rapidly falling photographic plate, the instantaneous value of the current being recorded simultaneously on the same plate by means of an oscillograph. The small quick variations of the current through the arc were produced by passing the oscillatory discharge of a condenser in series with a self-induction through it, so that the arc current consisted of a large constant part on which was superimposed a small ripple which died away after a few oscillations. By this method I find that in an eight-ampere solid arc a distinct variation is produced in the light emitted by both the + crater and the vapour column when the amplitude of the variation of the current from the mean is only 3 per cent., and the frequency of these superimposed variations is as large as 4,300 ∼ per second. At this frequency the variation in light became indistinguishable when the amplitude of the variation of the direct current was reduced to 2 per cent. Owing to the difficulty in estimating the points of maximum density in the band on the plate which represents the light emitted in consequence of the smallness of the variation of the current and therefore of the light, I was unable to be certain whether the maximum light lags behind the maximum current; but if it does, the lag is very slight, not exceeding 1/10000 second for an eight-ampere solid arc. It must be remembered that the above variations of light are those of the actinic rays which affect the photographic plate; the visual rays will probably vary in a similar manner, though possibly not to the same extent.

Effect on the Craters Produced by Variations of the Current.—Mrs. Ayrton tells me that she noticed that the variations in the current used by Messrs. Frith and Rodgers, who superimposed an alternating current of 0·5 to 1·8 ampere R.M.S. value, at frequency of 100 ∼ per second on a 10-ampere direct-current arc, so altered the shape of the ends of the carbons that she could easily distinguish them from normal carbons formed without any variation in the current. I find that if the superimposed alternating current be reduced to 0·1 ampere under the same conditions, the ends of the carbons appear unaffected.

Effect on the Vapour Column Produced by Variations of the Current.—Sounds: Corresponding with each value of the current through the arc there is probably a definite cross-section of the vapour column, so that if the current varies rapidly through an arc of fixed length, the volume of the vapour will also vary and sound-waves will be given out. This, I believe, is the generally accepted explanation of the humming of the alternate-current arc. In the case of the direct-current arc, sounds are also emitted even when the variations in the current are very slight. For example, the variation of current caused by the commutator segments of a direct-current dynamo passing under the brushes can be heard in the arc. This variation of the current, caused by the commutator segments, even when in good condition, was found by Messrs. Frith and Rodgers in the case of a 5-kw. two-pole machine to vary between 2·5 and 9 per cent. of the mean current, according to the position of the brushes. Another striking example of how sensitive the arc is to small variations in the current is furnished by the fact that a Wehnelt interrupter, working an induction coil on the direct-current street mains, will cause any arc supplied by the same mains to give out the same noise as the

* Paper read before the Institution of Electrical Engineers.

† "Solid," "solid-cored," and "cored" arc mean, respectively, arc between two solid carbons, between one solid and cored, and between two cored carbons; the top or + electrode being always placed first.

Digitized by Google

interrupter itself, even when a considerable distance intervenes between the place where the arc is connected with the mains, and where the interrupter and coil are joined on, as observed by Herr Simon, Mrs. Ayrton, and Mr. Jervis Smith. It must be clearly understood that the arcs here referred to are normal silent arcs—that is, if they were supplied with a really steady current, they would have been practically silent.* In order to determine what variation in the current was necessary to cause the arc to emit a clearly audible note, the current from a high-frequency alternator, kindly lent by Sir D. Salomons, was superimposed on the direct current by the method shown in Fig. 1. The current from the alternator passes through a condenser, F, a dynamometer, D, and the arc in series; and it is practically prevented from flowing through the cells which supply the arc by the self-induction, L. The direct current is

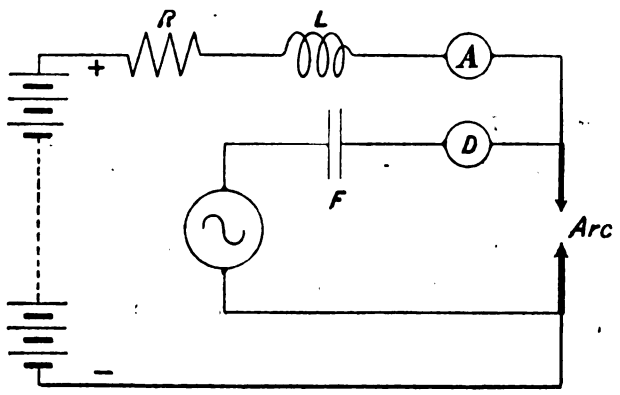

FIG. 1.

prevented from flowing through the alternator by the condenser, F. It was found by this means that a 10-ampere direct-current solid or cored arc, length 3mm. to 5mm., would produce a distinct note even if as small a R.M.S. current as 1/1000 ampere, as measured by D, was superimposed on the direct current for frequencies of the added current from a few hundred up to 8,000 ~ per second. Thus a variation of the order of 1 part in 10,000 from the mean current will alter the vapour column sufficiently to produce sound-waves. Further experiments with another alternator and R.M.S. superimposed currents of 1/20 to 1/10 ampere on a 10-ampere solid arc proved that the sounds only became inaudible at frequencies approaching 30,000 ~ per second. At these frequencies I am uncertain whether the arc had really ceased to give a note, as the ear fails to detect sounds of so high a pitch. This sensibility of the arc for very small changes in its current explains the fact that not only can rapid variations of current in any circuit supplied from the same generator as the arc be heard in the arc, but also variations of current which occur in a totally independent circuit supplied by a separate generator

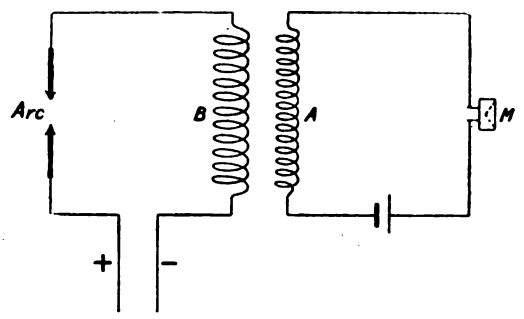

FIG. 2.

can be detected in the arc due to mutual induction between the two circuits.

Arc as a Telephone Receiver.—The fact that the arc is sensitive to such small variations in the current and over such a wide range of frequency, at once suggests that the direct-current arc might be used as a telephone receiver. This suggestion, which was made in a leader of the *Electrician* in 1899, had already been carried out by Herr Simon in 1898. The method used by Simon for superimposing a microphone current on the main arc current is shown in Fig. 2, in which A and B are two coils having mutual induction, and M, the microphone. The current through A varies when M is spoken into, and induces E.M.F.'s in B, which vary the current through the arc in such a way that it reproduces sounds and even speech distinctly. The variation of the current through the arc obtained by this method is not as large as it might be, as the E.M.F.'s induced in B have to send currents round the whole arc circuit, including any steadying resistances, and also through the self-induction in the armature, if a dynamo is used, instead of only through the arc where the varying currents are actually required. I have obtained a better result by replacing the alternator of Fig. 1 with a microphone and mutual induction, as shown in Fig. 3. A and B are the two coils of a mutual induction, F a condenser of about two or three microfarads, and L a high self-induction, the object of the self-induction being to prevent the microphone currents flowing round the cells instead of through the arc. With this arrangement and suitable arc conditions, to be explained later, the arc will speak sufficiently loudly and clearly to be heard at a distance of 10ft. to 12ft. in a quiet room. [Experiment.] The sound-waves given out by the arc are, therefore, of such an intensity that when the energy is spread over an area of 20ft. diameter, the ear placed

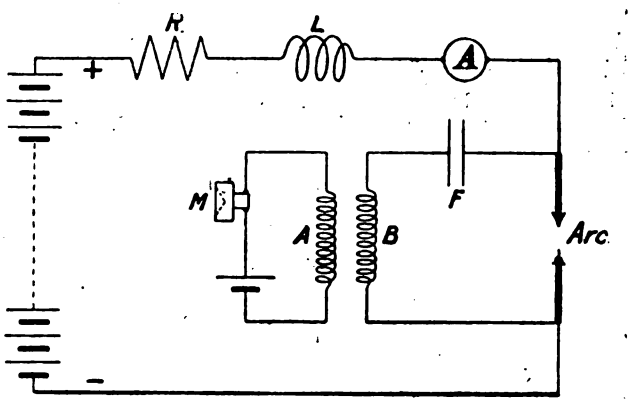

FIG. 3.

at any point can hear speech distinctly. It seems probable that if all the energy available could be collected and concentrated on the ear, very powerful sound sensations might be produced. The loudness of the sounds given out by the arc is increased by lengthening the arc, as this increases the volume of the vapour column which emits the sounds. It would also seem as if increasing the main current which increases the cross-section of the arc should also be beneficial, but experimentally I have not found any appreciable gain. The best results have generally been obtained with a current of 10 to 12 amperes, carbons 11mm. to 13mm., and an arc length of 20mm. to 30mm. To obtain these long lengths with ease it is necessary to use cored carbons or some other means of introducing foreign bodies, such as salts of potassium and sodium, into the arc, for there is not much doubt that the stability of the arc between ordinary cored carbons is due to the presence

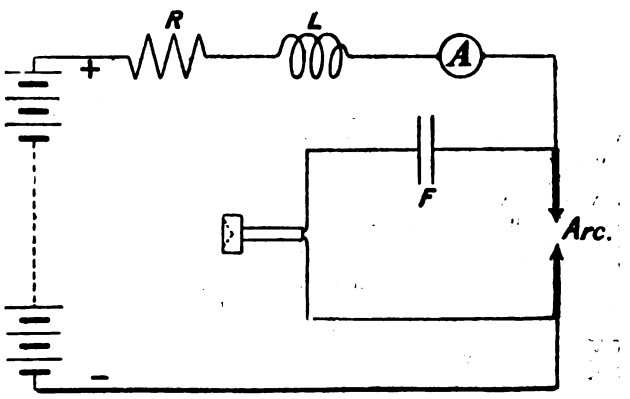

FIG. 4.

of potassium silicate in the core. These salts may be introduced either by soaking the carbons in their solution, or by using them as cores. Mr. Jervis Smith has recommended the insulator glass as a core, which I find works well.

Arc as a Telephone Transmitter.—Before leaving the subject of the use of the arc as a telephone, it will be convenient to consider its use as a telephone transmitter, though this subject strictly belongs to Part II. of this paper. Herr Simon found that if he replaced his microphone in Fig. 2 by a telephone receiver, any sounds made near the arc were heard in the receiver. In this case, as before, I find it preferable to modify his method by connecting the receiver in series with a condenser between the terminals of the arc, as in Fig. 4. A sound-wave striking the arc may affect it in two ways, either by vibrating the arc as a whole and varying its length, or the waves of condensation and rarefaction may alter the cross-section of the arc: both of these effects will tend to alter the apparent resistance of the arc, add hence vary the current through it. The sounds obtained in the telephone receiver when using the direct-current arc as a transmitter are not gene-

* Absolute silence is almost impossible, as the least want of homogeneity, or impurity in the electrodes, causes small spits and sounds.

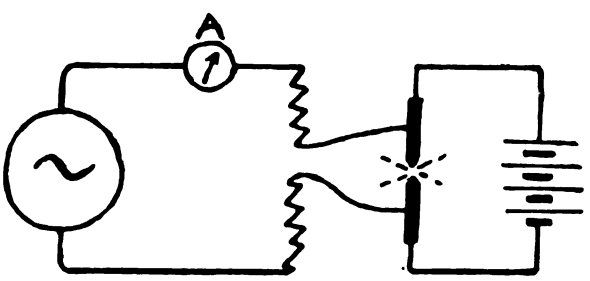
Digitized by Google

rally very satisfactory, as, besides not being very loud, they are obscured by the extraneous sounds due to the small spits and hisses which occur in the arc each time the air gets to the + crater due to any slight defect in the carbons. If a common pair of carbons be used containing cracks and impurities, the noise in the receiver is sometimes unbearable, although there is no outside source of disturbance of the current through the circuit. In all experiments on the arc as a telephone transmitter or receiver, it is essential that the current generator should be free from rapid variations, or extraneous sounds will be produced. If a dynamo has to be used, then the variations of the current produced by the commutator segments may be minimised by inserting a large self-induction in series with the arc, as in Figs. 1, 3, and 4. This self-induction serves the double purpose of keeping extraneous variations of the current out of the arc, and of preventing the variations we desire to observe from being dissipated in the source of supply. Thus we see that the direct-current arc is not only extremely sensitive to small variations in its current of almost any frequency, but also that it is affected by such small changes of outside conditions as sound-waves produce. Whether this sensibility can be turned to useful account in telegraphy or telephony remains for future experiment to decide.

(To be continued.)

Discussion.

Prof. W. E. Ayrton said the paper which they had just heard read had given him, as he was sure it must have given them, exquisite pleasure, not that he had any claim to be its author, but he had felt as pleased while hearing it read as if he had been the writer. Nor did he experience this pleasure only because he felt convinced that the experiments of that night, which were most useful for lecture purposes, would assist in the development of the electrical industry of to-morrow, but it was rather because it so rejoiced the hearts alike of professional men and of professors to find a student like Mr. Duddell, who so resembled the solid-carbon arc, for he was ever on the alert to catch at and magnify any hint which might come from nature or man. From Mr. Duddell's work—that presented some two years ago as well as the paper just read—they learnt much. Among other things, it had taught them how valuable was that research made about five years ago by Messrs. Frith and Rodgers. These experimenters, using



connections as shown in the accompanying diagram, proved that when an alternate current circuit was connected to the two electrodes of a solid-carbon arc supplied from accumulators, the alternating current was increased not only in one direction, as might have been expected, but in both directions. That investigation was made because he had pointed out to them that if they applied the methods which had been employed by various experimenters in certain conditions to an arc, they would obtain a negative answer for the resistance of the arc. Certain experiments carried out since had confirmed him in that view. Other experiments showed that whenever an arc was formed between solid carbons that $\frac{\delta V}{\delta A}$ was negative, whereas if they were cored carbons this ratio was always positive. A howl of indignant criticism followed, and if he and the experimenters had lived in the Middle Ages they would undoubtedly have been burnt. But there were other distinguished investigators who had the insight and the courage not to be drawn into this net of conventional antagonism, and among these were Prof. Gray, who is Lord Kelvin's successor, Mr. Oliver Heaviside, and the chairman of the Dublin section of the Institution (Pr. f. Fitzgerald), to all of whom they were very much indebted for so many suggestions. He did not propose that evening to consider whether or not what Messrs. Frith and Rodgers measured was the true resistance of the arc, because they would have an opportunity soon of going fully into that subject. But in justice to Messrs. Frith and Rodgers, and in virtue of the far-reaching principles which they had really brought to light, he desired to emphasise what they had obtained. Mr. Duddell had taught them what the significance of Messrs. Frith and Rodgers's work was. Dr. Hopkinson proved to them years ago that all alternators could not be run in series. Mr. Duddell had not only pointed out the importance of this result, but he had shown something further. He had demonstrated to them that the ordinary so-called perfectly silent arc supplied by the accumulators was like the mouthpiece of a flute, and that the application of a capacity in series with self-induction coils had shown some especially remarkable results. In this particular case the vibration was started and backed up when the capacity was in series with the self-induction coils. Already the author had shown them the practical result which was obtained from this. He had shown them how to improve a well-known instrument—the induction coil—and demonstrated the improvement over using a condenser joined up in the usual way, of employing a small motor so as to put the condenser across the gap immediately the break in the circuit was made. You then got a spark from five to ten times as long as was obtained by the apparatus used in the ordinary way. One other point came out in these experiments. About 10 years ago a paper read by Dr. Sumpner and himself before the Royal Society, pointing out that in the case of an alternating current arc, if they used solid carbons the true power given to the arc was considerably less than the apparent power. Subsequent to that he was pretty well convinced that in certain circumstances the direct-current arc behaved in the same way. In the case of a direct-current arc between solid carbons when hissing occurred, it was now established that the power factor was no longer unity. He was not sufficiently certain of this when he made the discovery, but now he was sure from the results of further experiments that with an arc supplied with accumulators—so called a direct-current arc—if the carbons were solid and there was a little hissing, then the power factor might vary 7 per cent. from unity. When he read this paper he thought the author had proved that a solid carbon direct-current arc was the most sympathetic soul he had ever met. But he was convinced now that this was not quite the case, for they had shown Mr. Duddell that evening that the sympathy of the arc was even exceeded by the sympathy of his audience.

Prof. J. A. Fleming thought it very difficult to decide who ought to be congratulated the more heartily that evening—the members of this Institution for having had an opportunity of hearing such a delightful paper from Mr. Duddell, or Mr. Duddell himself for having completed such a fine piece of work. This paper, he was sure, would have very important practical results in the future. The matter which had interested him most of all was the experiments with the continuous-current arc between metal electrodes, because he had been attempting something in the same direction himself, but he could not say that the result was the same as that arrived at by the author, because he had tried carbon only. Certainly, one of the most practically important parts of this paper was its final section as regarded metal switch contacts, and that would cause some heartsearchings amongst those who had been responsible for high-tension switches. It was generally believed up to now that the high-tension switch ought to have jaws which broke the arc as rapidly as possible, but according to the experiments carried out that night that was exactly what it ought not to do. He was particularly struck with the results that the author had obtained with his system of breaking the primary circuit of induction coils. One well-known fact in connection with induction coils was that they sometimes would not work well, when the number of cells used was increased. This was evidently because the current did not die away rapidly enough, and the arc was drawn out. The conclusion was that in the design of the contact breaker of induction coils, you must proceed in exactly the opposite way to what you should do in designing high-tension switches. He was sure this part of the paper would have great consequences.

The Chairman said he had intended calling upon several other gentlemen, as well as Mrs. Ayrton, to give the assembly the benefit of their views on the subject, but time did not permit of this. They wanted their remarks, however, and if they would send in what they had to say it would be published in the *Journal*. They had had extraordinary luck this session so far in having good papers to discuss, and the one they had had before them that night was almost the best.

CATALOGUES RECEIVED.

We have received from Messrs. Davies, Kent, and Stewart a list of their "flush" wall or floor sockets. These are specially constructed so that the surface of the sockets is quite flush with the floor or wall when the plug is removed. The sockets themselves are constructed in the best device entirely of porcelain, while the surface of the sockets can be varied to suit the wishes of the purchaser. We understand from the makers that they are stocking these in black or white English china, with plain surfaces for the floors, and with ornamental surfaces when the sockets have to be placed on the walls. Another type is also supplied with a brass surface, which will be most useful for floor work.

We have received from Messrs. Bergtheil and Young some illustrated leaflets concerning their "Bandy" type of electric motors. Amongst the motors illustrated is the "enclosed" motor for fixing on floors of both the two and four-pole type. They also make motors for connection to printing machinery, in which case much slower speeds are used and the number of poles in the motors increased. With the slow-running motors arrangements are also made so that they can be secured either to the floor or to the wall. In order to convince us of the large number of motors which have been supplied, the firm issue a list of the leading newspapers in the kingdom which use their system of electric motors and their control. About 35 newspapers are mentioned, from which we gather that the system must be eminently successful.

Digitized by Google

We have also received from Messrs. OFFORD and JEVONS a list of their patent time swithes, which are intended for use in arc lighting and on incandescent circuits when the lights have to be extinguished at certain predetermined times. The arrangements of the switch are such that the lights can also be switched on when required, and the whole of these operations are conducted with only one working dial. The apparatus used is a combination of an eight-day clock with mercury surfaces. The apparatus is contained in cast-iron cases, which protects it from damage, and is supplied in four different types. The operations of each of these is as follows: A, to switch on, or to switch off, only, either at fixed or variable hours; C, to switch on and off at fixed or variable hours; E, to switch on and off at variable hours, and to change over intermediately from arc to incandescent, or from full to partial light at a fixed hour; G, to switch on, change over, and switch off, all at variable hours. All the above are for circuits up to 250 volts, with specially insulated types, B, D, F, and H respectively, for use on circuits to 500 volts. As an example of the extended use that can be made of this apparatus, the firm state that the apparatus for switching "on" is suitable for making sub-circuits for lights or motors at a required (variable) moment where the mains are controlled from a centre, and the resetting done by hand; and "off" for breaking a circuit, such as for public arc or incandescent lights at daybreak; for shop window-lighting after closing hours; for burglar-proof lights to extinguish at daybreak; for public conveniences; for advertising signs; for changing over "station load" to battery sub-station without necessity for full capacity leads; for disconnecting a battery left on charge in a circuit at night-time; for cutting off current from electro-plating vats at a pre-determined moment; and for various motor-stopping requirements. The inverse operation of breaking or making respectively to be effected by ordinary means. The prices of the apparatus are reasonable, but we think objection may be taken to the use of the mercury contact switch.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

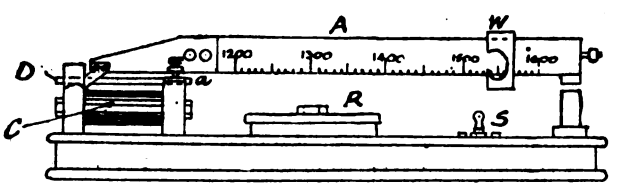
335. Explain how a shunt-wound exciter can reverse itself whilst exciting the field of an alternator. State probable causes. The alternator has claw type revolving field, and was working at light load.—E. P.

336. On switching on a motor to a single-phase alternating circuit, the volts appear to drop quite out of proportion to the increase in load. Why?—P. A.

ANSWERS.

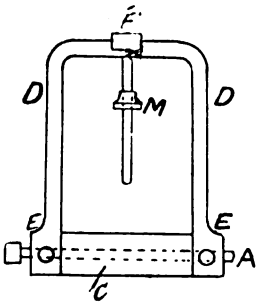
Question No. 329.—Describe and explain what you consider the best workshop method of determining the values of B and H, and for plotting B and H curves of wrought iron and steel.

Answer to No. 329 (*awarded 7s. 6d.*).—For workshop use it is only generally needful to test the permeability of different samples of wrought iron and steel with a known value of H, and the best method to do this is by using Prof. Ewing's magnetic balance. The balance consists of a graduated beam, A, pivoted at *a*, which is divided up into divisions for B, reading from 1,200 to 1,600, a sliding weight, W, for adjusting. Under one end of the beam is an electromagnet, C, which is excited by a current which gives exactly 20 C.G.S. units of magnetising force. One pole of this magnet is rounded, the other pole having a V-shaped notch cut into it. On this magnet rests the piece of iron or steel to be tested, D. This rod passes through the end of the beam, and must be turned ¼in. diameter and 4in. long. When the beam pulls the iron rod away from the rounded pole of the magnet, the other end of the rod remains in the V-shaped notch, forming what is called a magnetic hinge. R is a regulating resistance; S is a reversing switch to get rid of any residual magnetism before a test is made. A small storage battery is also



required. To measure the permeability of a sample of wrought iron or steel, the balance is first set by the standard rod which is supplied with the instrument, the current being adjusted until the tractive force corresponds to the known value of B which a force of 20 C.G.S. units produces in the standard. Remove standard and substitute sample to be tested; adjust sliding weight, W, until the beam just drops, and the value of B with a known value of H can be directly read off the graduated scale. This is a good practical method, as it has been found that if a sample is good or bad at this force it covers the whole range. The standard rod serves as an ampere-meter, and no other instruments are required.

For a practical method of determining B with different values of H, we are also indebted to Prof. Ewing, whose permeability bridge meets all the requirements. This is a method of determining the B H curve by comparison with a standard rod, whose B H curve has been previously determined by the ballistic method. The main principles of this instrument are shown in the sketch, where A is one bar



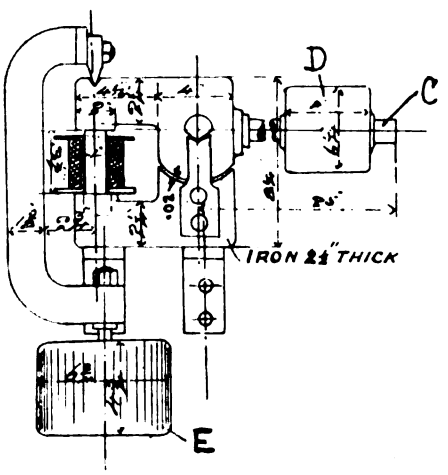
whose B H curve is known. The bar to be tested is parallel to the bar, but is not shown in the elevation. These bars must be 12·56cm. (4 π) long. These are slipped into two parallel magnetising coils, C. The ends of the rods are joined by two yokes, E E, are held tightly in position by means of set screws; from these yokes project two long iron arms, D D, which nearly meet; in the gap is a box containing a magnetic needle, F; M is a controlling magnet. The magnetic needle serves as a detector to show when the yokes are at the same magnetic potential. Such a condition will only exist when the magnetic induction in the two rods is the same. In that case the magnetic circuit will be complete in itself; the lines that got from right to left in one bar will return from left to right along the other. If the rods have the same permeability, this state of balance will be produced with equal ampere-turns for each rod; if not, balance can only be obtained by altering relative number of ampere-turns. To do this, the number of ampere-turns in the magnetising coil of sample rod is altered by means of switches, while the same current passes through both coils. To prevent the current altering while the adjustment is being made, the switches are furnished with a second set of contacts, which throw in compensating resistances as the number of magnetising coils is reduced, so that the total resistance of the circuit is unchanged. The number of turns in the magnetising coil of the standard is 100, hence the magnetising force due to this coil with a current of one ampere equals 10 C.G.S. units, so that any desired magnetising force may be supplied by means of an ampere-meter and adjustable resistance.

The number of turns on the sample bar may be increased to 210 by means of a switch provided on the instrument as before. The relation B to H is known for the standard bar, we know the current which is enough to show at

Digitized by Google

what value of the induction, B, the comparison is being made, and B is, of course, the same for both rods when the condition of balance is produced. The number of turns on the other rod gives by its ratio to 100 the ratio of magnetising force for that rod to known force applied to standard rod; hence a point in the B H curve of the rod under test is determined, and by changing the current as many points as may be wished may be obtained, from which the curve may be plotted. In cases where rod to be tested is much inferior to the standard, a switch is provided for reducing the turns on the standard rod to 50, when H becomes 5 C.G.S. units instead of 10 G.C.S. units per ampere.—W. A. J.

Answer to No. 329 (*awarded* 7*s.* 6*d.*).—There is in use at the works of Messrs. E. Scott and Mountain, Limited, Newcastle-on-Tyne, an apparatus for measuring the permeability of iron and steel used in dynamo magnets, which has given very reliable and accurate results as tested by measurements made on the actual machines from the magnets of which the test samples were cut. It is built substantially on the lines of the apparatus described in Chapter IV. of "Continuous-Current Dynamos" by J. Fisher-Hinnen, but different in a few details. It is liable to no serious errors due to external magnetic fields, is direct reading, easily calibrated, and easily used and understood. It requires only about 20 minutes to make a complete series of measurements necessary to plot the B and H curve of a sample of iron right up to the highest values of B used in ordinary dynamo work. The samples used are only 1in. in diameter and 3½in. long. A point is left on the side of a magnet casting, from which three or four of these samples are cut and turned to the above dimensions. An average of the readings from each is taken and the curve plotted from these. The dimensions of the appa-



ratus are given on the sketch. The weight of D is 14¾lb., and the weight of the balance weight, together with its suspending arm, is 49¼lb. The apparatus is constructed in accordance with the law of magnetic traction, which, stated briefly, is that a magnet of cross-section A square inches, magnetised to a density of B lines per square inch, can develop a pull of $\cdot 0000000133 \times B^2 A$. The scale on C is calibrated by hanging known weights on E and marking the position of D when balance is obtained. The arm, C, can thus be engraved to read lines per square inch directly. A second scale is engraved on C for the higher values of B. This scale is used when the weight, E, is lifted off, thus enabling the higher values of B to be measured with a shorter arm than would otherwise be possible. With the apparatus of dimensions shown in the sketch, values of B from 30,000 to 100,000 lines per square inch are read on one scale and from 80,000 to 120,000 on the other. A correction worked out for the apparatus as shown gives a number of ampere-turns per inch to be subtracted from the observed number equal to $\cdot 00012\ B''$. The ammeter used to measure the current in the magnetising coil is graduated in ampere-turns per inch length directly. In using the apparatus the weight, D, is set to a point on the scale of C, and the current gradually decreased, by means of a carbon rheostat in circuit with the coil, till the yoke breaks away from the sample. It is found to be quite impossible to get accurate readings by keeping the current constant and shifting weight D, as the disturbance caused by moving D makes the readings very inconsistent. The curves obtained from this apparatus have proved quite accurate enough for ordinary dynamo designers' requirements, and the rapidity with which they can be obtained makes it a very useful workshop method of obtaining B and H curves.—J. L.

Answer to No. 329 (*awarded* 5*s.*).—Undoubtedly the best workshop method of determining the figures for a B and H curve is by a permeametre (as designed by Prof. Silvanus P. Thompson). Fig. 1 shows the construction of this instrument. A is a block of soft iron, the centre of which is cut away and a hole about ⅞in. diameter bored through upper part; through this hole is fitted a brass tube, on which is wound a coil of wire which is connected to a battery through an ammeter and variable resistance. The iron to be tested should be turned circular and fit the brass tube.

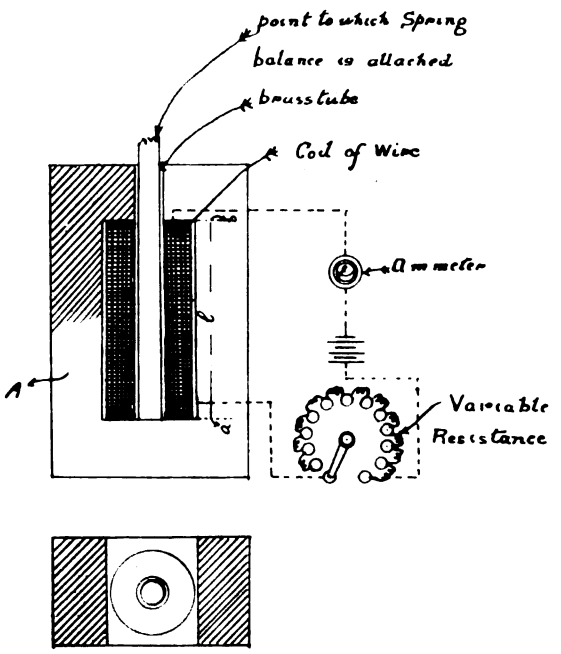


FIG. 1.

One end of the rod is attached to an ordinary spring balance, and the other rests against the inner part of iron frame. This end of the iron should be very carefully faced, as also should that part of iron frame with which it makes contact. The method of taking the readings is as follows: Lay the permeametre on its side so that the iron rod occupies a horizontal position, switch on the current, pull steadily on the spring balance till the rod breaks away from the iron frame. Note pull required. Take these readings with varying strengths of current, and we get a series of values for B of the iron rod, thus—

$$B = 1{,}317\sqrt{\frac{P}{A}}.$$

P = pull in pounds;
A = sectional area of iron rod in square inches

$$H = \frac{4\ \pi\ T\ C}{10\ \ l}.$$

l = length of iron rod between points a and b;
C = current in amperes;
T = number of turns in coil.

This is a very quick method of determining the values of B and H, and quite accurate enough for commercial purposes.

Another method, due to Fisher-Hinnen, and described in his book on "Continuous-Current Dynamos," is admirably adapted for the workshop; it possesses one slight disadvantage compared to the first method described—*i.e.*, it has to be graded. The principle of the instrument will be apparent from Fig. 2. A represents piece of iron to be tested, round which is wound a coil of wire; the ends of the test piece require very careful planing. The arched pieces, C D, are made of much larger section than the test piece, and rest on two knife-edges. The purpose of piece marked E, and weight F, is to maintain equilibrium whilst the lever, G, is adjusted, in order to use instrument

Digitized by Google

while F is fixed at a certain value of B. Then the current in the coil is reduced until armature of magnet is just released, or the exciting current may be kept constant, and

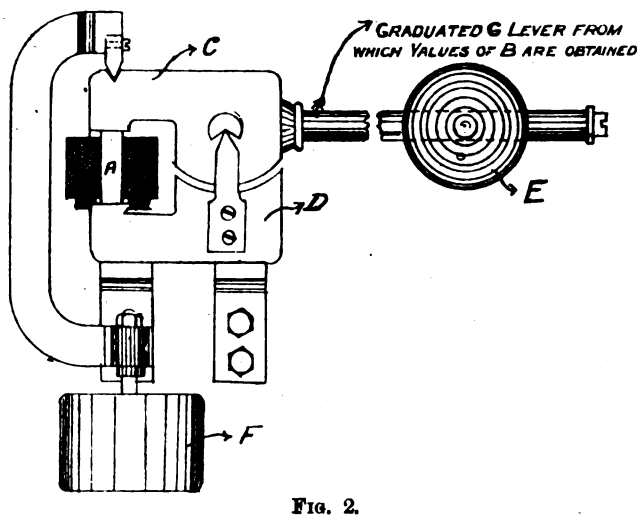

FIG. 2.

position of weight altered till the armature is released. The value of H is determined in the same manner as before described.—R. F. W.

Question No. 330.—When feeding boilers with very soft feed water, in which there is a good deal of peat acid, what kind of feed pipes would you recommend (1) taking the outlay into consideration, (2) disregarding outlay altogether?

Best Answer to No. 330 *(awarded* 10*s.)*.—The enquirer's experience with peat water must be somewhat unusual, as the writer has generally found that the water collected from a peat district is of a very satisfactory character for the purpose of feeding boilers, and is mostly free from both hardness and acidity. A notable example of this is the water from Loch Katrine, which is supplied from a peat district, and is considered to be probably the best feed water in this country. The scientific mode of procedure for dealing with boiler feed water suspected of containing deleterious matter is, first to have it analysed quantatively, and the amount of objectionable matter per gallon of water ascertained. Then, either in the feed tank or in a separate tank, and before admission into the feed tank, a substance should be introduced which will neutralise the objectionable constituent. The most general disadvantages met with in feed waters are due to hardness, arising from the presence of lime in suspension, or acidity. The hardness is usually eliminated by treating the water with lime, and the acidity by treating it with common soda. The water in question should be treated before admission to the boilers with the latter substance, and in a sufficient quantity to destroy its acidity, in which case the feed pipes could be of the ordinary material and construction, and no additional outlay would be incurred through them. It may in this or ome special case, however, occur that there is not sufficient available space adjoining the boiler plant to admit of the necessary settling tanks being put down for efficiently treating the water prior to its admission. The acidulated water would, therefore, have to be admitted through the feed pipes to the boilers and treated in the boilers to destroy the acidity; consequently the pipes would be subjected to the corrosive action of the acid, and if there is no question of outlay the best course would be to have the pipes made of copper, as this material is capable of resisting the corrosive action of acid.—E. T. J.*

Answer to No. 330 *(awarded* 5*s.)*.—When feeding boilers with soft feed water containing peat acid, the pipes through which the cold water is pumped are inclined to get choked up with a sort of growth something after the nature of green slime that one sees on stagnant ponds. To minimise this trouble I should, in the first case, where first cost is an important consideration, advise extra large feed pipes of cast or wrought iron with cleaning-out apertures arranged so that the pipes could be cleaned out periodically. In the second case, disregarding outlay altogether, I should recommend steel pipes lined with lead, as this growth will not adhere to this latter metal.—W. J. C.*

COMPANIES' MEETINGS AND REPORTS.

NERNST ELECTRIC LIGHT.

The first ordinary general meeting of the shareholders of Nernst Electric Light, Limited, was held on Wednesday last at the Westminster Palace Hotel, S.W., Sir Henry C. Mance presiding.

The **Secretary** (Mr. G. Opitz) read the notice convening the meeting, and also a notice from Mr. Zusman, one of the directors, in which he stated that he would move resolutions requiring the directors to invite the managing director to resign his office as such, to resign his office as director of the Company, and to allow Mr. Zusman to have unrestricted access at all reasonable times to the books, papers, and documents of the Company.

The **Chairman** expressed the pleasure it gave them to see Prof. Nernst with them again, and offered congratulations to him on his having been awarded the grand prix at the Paris Exhibition. He proceeded to review the balance-sheet. It must be remembered that the accounts covered a period of 19 months. At the statutory meeting of the Company, Mr. J. Swinburne had advised them not to rush the lamps on to the market, but predicted that after careful experiments to determine the best commercial form lamps should be ready for sale by this autumn. But for the fire his predictions would have been realised, and in spite of that the lamps had now reached a commercial state. He did not think the time taken to reach this stage was long considering the importance of the work to be done, and their business might have been much damaged if the lamps had been issued in a crude form, and hence had been likely to bring discredit on them. In perfecting the lamp they had not been behind the other holders of licenses. Thus Mr. Westinghouse, the General Electric Company of Berlin, and Messrs. Ganz and Co., of Budapest, had the control of these patents 12 months before they had. Messrs. Ganz say they would not be prepared to issue lamps before April or May next, and Mr. Westinghouse had refused to discuss the prices to be charged for lamps because he had not any ready for sale. The Berlin company had only just begun to rent lamps to the public. He was firmly convinced of the value of the lamps, even of the type which required preliminary heating by a spirit lamp or match. He had used these lamps in his private house, and found that on an average they lasted over 500 hours. Their own technical advisers, however, believed that it was essential to make the lamps automatic, and hence had devoted their energies to perfecting the lamps exhibited at the offices of the Company that day. They proposed to sell their lamps outright, and it might interest those present to know that the extent of lighting in the various countries they could supply appeared from report to be this: that there were 38,000 arc lamps and 5,000,000 incandescent lamps now in use. They had obtained 47 patents in various parts of the world, and applications for 14 other patents were still pending. He then referred to the good work done by their managing director, Mr. Drake, in organising their various departments, and to the disputes which had arisen between him and Mr. Zusman. He (the chairman) took the responsibility of refusing Mr. Zusman access to the books, because they were bound to exercise great secrecy over the details of the lamps. He also objected to one director interfering with the staff as likely to break discipline. At the time the objections were made, however, Mr. Zusman was informed that he could obtain copies of what he wanted after consulting the Board. At the next Board meeting Mr. Zusman submitted a protest, declaring that the past conduct of the Company had been opposed to its interests, and had been a policy of inanition, and that the managing director had been guilty of neglect and mismanagement, and had subordinated some of the best interests of the Company to those of another company. Turning to the question of a factory, they hoped to secure the English patents and thus be allowed to manufacture in this country, when they could supervise the work better than if the factory were abroad. Their right to the royalty on lamps sold in England should help them in coming to some such arrangements when the English company was established. If the directors were to leave the Company that day they would leave a valuable asset. By not establishing factories before they were actually required, and by not sending out agents prematurely to advertise an invention which spoke for itself and required no advance advertisements, they had saved the Company considerable sums. He begged to moved the adoption of the report.

Mr. Bernard Drake seconded the motion, and gave a *résumé* of the state of the technical work of the Company when it was formed by Mr. Zusman, the promoter. The lamps then shown were of large candle-power only. From these they had developed the 16-c.p. lamps exhibited at their offices that day. The time spent in so doing was well spent as it prevented them issuing lamps before they were in the best possible form, and they had now standardised what they believed would be a most successful lamp. Many difficulties had been surmounted in the process of development, such as the undue heating of the metallic connections to the glower, the heating of the holders, etc. Mr. Zusman had stated that he would bring charges against the speaker, but he had not adopted the gentlemanly method that might have been expected from him of disclosing the details beforehand, so that he (the speaker) might have had an opportunity of looking up the supposed facts. He did not therefore propose to refer to the matter until Mr. Zusman and the supporters he had recently qualified with shares had finished their attacks. When the attack was first made he had placed his resignation as managing director in the hands of his colleagues, but they had refused to accept it.

Digitized by Google

Mr. Ben Zusman then read his charges, which took over an hour. He declared his opinion that the past conduct of the undertaking by Mr. B. M. Drake had been opposed to its true interests, and that its future was foredoomed to failure if he was permitted to retain any longer the position he now occupied as managing director, or if he was allowed to remain a director at all. The detail charges related to infrequent attendance at the offices of the Company, preferential placing of contracts for materials, and undue favour shown to the Electric Resistance and Heating Company. The heaters owned by this latter company had been discovered in the Nernst Lamp Company's laboratories, and it was agreed that this latter Company should get all the heaters they required at cost price. Mr. Drake afterwards wrote a letter in which it was suggested that the preferential rate should be 15 per cent less than to other people. This letter was stopped by the chairman. Finally, Mr. Zusman said his last charge was that Mr. Drake's overbearing manners and absence of tact were continually making enemies. He had dispensed with the services of the only people who knew how to make a practicable lamp, and had brought about the resignation of Prof. Nernst as technical adviser. He had entrusted the Company's orders to incompetent contractors at 60 per cent. higher than could be obtained from competent firms elsewhere, and had placed orders of the Company with a view of benefiting another undertaking. He concluded by moving an amendment that the report should be received but not adopted.

Mr. August Cohn seconded the motion, as one who was responsible for a great proportion of the preferred shares, and expressed the opinion that if Mr. Drake remained manager of the concern they would never get a dividend He added that the fees of the directors were quite out of proportion to the position of the Company.

Mr. Ronald Power considered there was a very strong *primâ facie* case for Mr. Zusman's action, and he thought the shareholders ought to insist on the enforcement of an intelligent commercial policy. He challenged the directors to show that any practical step had been taken to establish foreign agencies in countries where they were entitled to sell these inventions.

An animated discussion followed, and a desire was expressed that Mr. Drake should be given an opportunity to reply to the charges that had been made against him.

The **Chairman** pointed out that the charges had been carefully prepared, and many of them he had never heard before. The meeting could hardly expect Mr Drake to give the necessary explanations now. Mr. Zusman had been many weeks preparing these charges, and it was not fair to ask any man to answer them at a moment's notice.

After further discussion, it was decided to adjourn the meeting for a month, and the proceedings, which had lasted for three hours, concluded.

MARCONI'S WIRELESS TELEGRAPH.

On Tuesday Major Samuel Flood Page, managing director, presided at the fourth ordinary general meeting of the Company, held at the offices in Finch lane, E.C.

In moving the adoption of the report and accounts (which we published in our last issue), the **Chairman** said the accounts covered a period of 13 months, as the directors had decided to change the date of the financial year from Aug. 31 to Sept. 30. The only change with regard to the capital was that £1,000 more ad been issued and that was part of the money included in the note which stated that of the unissued shares 12,500 were subject to the option reserved by an agreement of Aug. 30, 1900. That transaction had been closed, and the Company had received £37,500, but only £1,076 came into the present accounts. After dealing with the other items in the accounts, the Chairman referred to the German patents. Everybody who had a German patent thought he had got something of great value, and this was especially the case on the Continent. About 12 months ago it looked as if the Company was manifestly in difficulties with the German Patent Office. Dr. Fleming and he, however, went to Germany and demonstrated to the complete satisfaction of the German officials that the portions of Marconi's apparatus which they had regarded as anticipated were of no use at all to wireless telegraphy. The result was that the Company got the German patents, which were received a few days ago, accompanied by a letter from the patent agent stating that he thought the Company's further applications for patents stood a good chance indeed of being granted. The Chairman went on to state that the Board of Trade committee appointed to consider the question of introducing the German and United States system of granting patents into England had no intention whatever of making such an introduction into this country. There was no more improper power than to give paid officials the authority to reject applications for patents. Referring to the arrangement by which this Company received £100,000 fully paid shares from the International Marine Communication Company, the Chairman said it would be most disappointing to him if he or his predecessor had not some day to congratulate the shareholders of the Wireless Telegraph Company upon the great value of those shares. This was the first time they had had a profit and loss account, and this clearly showed they were actually earning money. Referring to the large sum of £5,926 for salaries and directors' remuneration, he must remind them that it was absolutely necessary that they should keep an educated technical staff in order to carry out the work and experiments, upon the success of which the fortunes of the Company very materially depended. After considerable experience of the Company, he might say that the expenditure was most moderate, and without it they could not have attained the position they now held of being prepared to undertake almost any work placed in their hands. Several members of the Belgian Cabinet were greatly interested in wireless telegraphy, and he thought their action in supporting this Company in its efforts to demonstrate the value of the invention would be the means of influencing other governments. The chief business of the year was undoubtedly the fact that they had completed the whole of the 32 sets of apparatus for her Majesty's navy. The captain of H.M.S. "Vernon" had been good enough to forward the directors a letter expressing satisfaction with the system, and with the rapidity with which it had been completed. The ships now fitted with the apparatus were moving certificates of Marconi's wireless telegraphy. He had not the slightest doubt that before long commercial companies would follow the example set by her Majesty's Government. With regard to the works at Chelmsford, they could now turn out all the apparatus required during the next 12 months. By the end of January next he hoped they would be able to prove to the Admiralty the value of the new patents, and it was his firm conviction that the business of the Company was certain to extend, and to become one of the greatest instances of the application of science to industry.

Mr. W. W. Goodbody having seconded the motion, the report was unanimously adopted without discussion.

The retiring directors, Mr Guglielmo Marconi and Mr. John Mooney, were unanimously re elected.

An extraordinary general meeting was then held for the purpose of moving a resolution that the directorate be increased from seven to ten. The **Chairman** said they wanted gentlemen who had influence with the Government, and therefore it was proposed to elect Mr. Henniker Heaton, M.P., Sir Charles Euan-Smith, and Mr. Albert Ochs to the Board.

Mr. J. F. Bannatyne seconded the resolution, which was carried unanimously.

A vote of thanks to the chairman concluded the proceedings.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

An ordinary general meeting of this Company was held this week at the Cannon-street Hotel under the presidency of the **Hon. Henry Marsham**, who said that on the present occasion the accounts were for a full period of 12 calendar months. The accounts would, he thought, be considered satisfactory. They could certainly not have come before the shareholders under such favourable conditions had they not, to meet the high price of raw material, taken the unpopular step of raising the selling price of their goods. Their customers had tacitly acknowledged the necessity of the Company's doing so by the continued support they had given it. The directors intended returning to more reasonable selling prices at the earliest opportunity. The price of indiarubber showed signs of falling; the price of guttapercha, however, maintained its high standard, and they did not anticipate lower values in that product. With regard to the Pacific cable, though they had not yet received any official reply to their tender, they must consider the matter closed so far as they were concerned. They must not, however, be despondent. The laying the Pacific cable would supply an important Imperial want, and, as especially affecting that Company, would widen the market of British cable manufacturers. He moved "that the report and accounts for the financial year ended Sept. 30 last be received and adopted, and that a dividend of 15s. per share, free of income tax, payable on the 14th inst., be now declared."

The motion was carried unanimously.

ELECTRIC RESISTANCE AND HEATING.

At the first ordinary general meeting of this Company, held at Winchester House on Tuesday last, the **Chairman** (Mr. Cyril Wanklyn), commenting upon the first annual report, said there was still some hope that their process had a future before it. The one feature of the Company's business upon which they could look with unalloyed satisfaction was that the material patent of the Company had been granted in all the countries enumerated in the prospectus except Germany, Denmark, Norway, and Russia, but though they had been unable to obtain the material patent, they had obtained a large number of apparatus patents. A great deal of work, trouble, and anxiety had been entailed in the progress of their endeavour to prove the value of their process, and they had had to meet difficulties one by one. The failure of the Company to receive payment in full in respect of 8 550 shares, relied on as part of the working capital, was really a knock-down blow to the Board. More than a third of the working capital (£6,500) had never come into the coffers of the Company. The want of the capital left them at a point at which they were almost bound to prove what the process could do. If the subscriptions for the 8,550 shares were not received, there was only one course before them, and that was liquidation, with a view to reconstruction. If they could overcome two or three of the obstacles that had appeared in the details of the manufacture, he believed there was a very good future before the Company. He moved the adoption of the report and accounts.

Captain Bax seconded the motion.

In reply to Mr. Guldalla, the **Chairman** said the vendors received from the Company £32,500 in cash and £62,500 in shares.

The report and accounts were adopted, and the chairman and Lieut.-Colonel W. T. Ellis were re-elected auditors.

Digitized by Google

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS.

The annual meeting of the Douglas Southern Electric Tramways, Limited, was held on Tuesday at Manchester, under the chairmanship of Mr. T. J. Hutchinson. The report showed a profit on the year's working of £1,617. 14s. 9d.

The **Chairman** said efforts were being made to bring their line into more immediate touch with Douglas town, and they were hoping to make such arrangements with the Douglas Corporation as would be for the good of the people of Douglas. They regretted there was no dividend for the ordinary shareholders, but 6 per cent. was being paid to the preference shareholders, and if that were divided equally between the whole of the shareholders it would amount to nearly 4 per cent. all round. The Company was solvent, and the shares were likely to improve in value.

The report was adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Asuncion (Paraguay).—The Municipality invite tenders for the installation of the electric light in the town. Tenders by Jan. 15, 1901.

Southampton.—The Tramways Committee have instructed the town clerk to arrange for tenders to be obtained for six additional cars.

Ploesti (Roumania).—The Municipality invite tenders for the installation and working of an electric tramway for 30 years. Tenders by Jan. 3, 1901.

Aberdeen.—The Electric Lighting Committee invite tenders for the supply and erection of storage batteries. Tenders by Dec. 22. Details in our advertisement columns.

Madrid.—The Department for Agriculture, etc., invite tenders for the installation and working for 60 years of an electric tramway from Insepets to Fogas and Boranova. Tenders by Jan. 7, 1901.

Hendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Swindon.—The Corporation invite tenders for three high-speed triple-expansion steam dynamos, one balancer, and one motor-generator. Tenders by Dec. 24. Details in our advertisement columns.

Edinburgh.—The Corporation invite tenders for the extension (about 100 lamps) of the electric lighting installation at the City Chambers. Tenders by 31st inst. Details in our advertisement columns.

Farnworth.—The Urban District Council invite tenders for eight 66 passenger tramcar bodies, motors, undertrucks, controllers, etc. Tenders by Jan. 10. Details in our advertisement columns.

Harrogate.—The Corporation invite tenders for two high-pressure 30ft. by 8ft. 6in. Lancashire boilers, with fittings complete, and economiser. Tenders by Dec. 25. Details in our advertisement columns.

Battersea.—The Council invite tenders for the supply of ordinary and prepayment electricity meters, in accordance with specification No. 10. Tenders by Feb. 1, 1901. Details in our advertisement columns.

Brighton.—The Council invite tenders for the supply of unarmoured and armoured lead-covered electric cables during the year ended Dec. 31, 1901. Tenders by Dec. 24. Details in our advertisement columns.

Partick.—The Corporation invite tenders for the construction, supply, and erection of steam dynamos, battery-charging motor, booster, and balancer. Tenders by Jan. 7. Details in our advertisement columns.

Ayr.—The Corporation invite tenders for the work required in forming permanent way, rail-laying, roadwork, etc., of about 5¾ miles of electric tramways. Tenders by Dec. 28. Details in our advertisement columns.

Middleton.—The Corporation invite tenders for superheaters, economisers, feed pumps and pipes, tanks, steam and exhaust pipes, valves, and accessories. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Rathmines.—The Electric Lighting Committee invite tenders for the supply and erection of various plant for the extension of the municipal electricity works. Tenders by Jan. 10, 1901. Details in our advertisement columns.

Kertch.—The Municipality invite tenders for the installation and working of an electric tramway. Particulars may be obtained from the Manager, Bank of Commerce of Azoff Don, at Kertch, Russia. The town has a population of 50,000.

Bradford.—The Corporation invite tenders for the erection of an electric tramcar shed at Duckworth-lane, Manningham. Drawings, etc., may be seen at the office of the City Architect's Department, Chapel-lane. Tenders by Dec. 24.

Worthing.—The Corporation invite tenders for the supply and erection of a main switchboard. Specifications, etc., can be obtained from Messrs. Burstall and Monkhouse, 14, Old Queen street, Westminster, S.W. Tenders by Dec. 31.

Belfast.—The Harbour Commissioners invite tenders for 10 tramway trucks, each capable of carrying a weight of 10 tons on a 3ft. gauge. Further information may be obtained from the harbour engineer, Mr. G. F. L. Giles. Tenders by Jan. 7.

Tooting.—The Metropolitan Asylums Board invite tenders for the execution of certain wiring and other works in connection with the proposed electric light installation at the asylum now in course of erection at Tooting Bec. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of tramway bonds. Specifications, etc., may be obtained on application to Mr. J. M. M'Elroy, general manager, Tramways Department, Town Hall, Manchester. Tenders by Dec. 22. Details in our advertisement columns.

Thetford (Norfolk).—The Town Council invite tenders for supplying the wiring and fittings necessary for the electric lighting of the new town hall according to plan and specifications, which can be seen at the office of Mr. John Houchen, town clerk, London-road, Thetford. Tenders by Jan. 1, 1901.

Leeds.—The Lighting Committee invite tenders for electric lighting plant as follows: (Section A) two sets, each comprising engine of 2,000 b.h.p., two-phase alternator of 1,400 kw. capacity, and exciter; (B) two sets of surface-condensing plant. Specifications, etc., may be obtained from Mr. Harold Dickinson, manager of the department, 1, Whitehall-road, Leeds. Tenders by Dec. 31.

Manchester. — The Manchester Ship Canal Warehousing Company, Limited, invite tenders for the supply, delivery, and erection of 22 electric jib cranes required for work at the new transit shed, No. 8 dock, Manchester. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, M.I.C.E., chief engineer to the company, 41, Spring-gardens, Manchester. Tenders by Jan. 4.

Winwick (near Warrington, Lancs.)—The Committee of Visitors for the County Asylum invite tenders for (Contract No. 3) wiring, etc., including ring main and feeders, sub-main, lamp circuits, switchboards, distribution boards, fittings, etc. The drawings, etc. can be inspected at Winwick Hall, and also at the offices of the architects, Messrs. Crisp and Oakley and W. S. Skinner, Edinburgh-chambers, Baldwin-street, Bristol. Tenders by Dec. 29.

Worthing.—The Electric Lighting Committee invite offers from any person, firm, or company willing to instal, equip, and maintain a system of electric tramways in the borough, with power to the Corporation to acquire the same at any specific date upon agreed terms, such offers to specify the price to be paid for current to be supplied from the central station of the Corporation electric lighting works. Tenders by Dec. 31. Details in our advertisement columns.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

Wolverhampton.—The Tramways Committee invite tenders for the supply of the necessary materials and labour for the construction of tramway track and contingent works in Tettenhall-road, New Hampton-road, Waterloo-road, Darlington-street, Queen-square, Lichfield-street, Fiveways, Piper's-row, Bilston street, Cleveland-road, and Bilston-road to the borough boundary, amounting to a route length of about 4½ miles, mainly double track. General conditions, etc., may be seen at the office of Mr. J. W. Bradley, M.I.M.E., borough engineer and surveyor, Town Hall, Wolverhampton. Tenders by Jan. 15.

RESULTS OF TENDERS.

Stockport.—A contract has been entered into with Dick, Kerr, and Co., London and Preston, for 20 double-deck cars.

Ilford.—The Council have accepted the tender of H. and G. Measures, Croydon, at £1. 10s. each, for lamp columns.

Bristol.—The tenders of Higginbottom and Mannock and of Ferranti, Limited, for switchboards have been accepted.

Bolton.—The Tramways Committee have accepted the tender of Mr. J. W. Witter for heating carsheds at Shiffnall-street.

Maidstone.—The Electric Lighting Committee have accepted the tender of Cole, Marchent, and Morley, Limited, at £1,209, for surface condenser and feed-pumps (Section C).

Burton.—The Corporation have accepted the tender of Geipel and Lange, Victoria-street, Westminster, for the supply of a 400 kw. alternator engine and condensing plant, at £3,335.

Heywood.—The Council have accepted the tender of W. J. Fryer and Co., Limited, London, for wiring premises in Heywood, in accordance with the wiring regulations adopted by the Council.

Portsmouth.—The Corporation have accepted the tender of Macartney, McElroy, and Co., London, at £18,280, for the overhead electrical equipment of tramways in the borough of Portsmouth, and extending to Cosham, Hants.

London County Council.—The Council have accepted the offer of Macfarlane and Co. to erect in position, at £178. 10s. 6d., the lamp standards now being manufactured by them under contract for the electric light installation for the Victoria-embankment and Westminster Bridge.

Digitized by Google

Southampton.—The Council have accepted the following tenders: Westinghouse Company, for supplying equipments for six more cars at £253. 13s. per car, being the same price as paid before; Milnes and Co., for supplying bodies for six additional cars at £290 each, being an increase of £43 on the price previously paid.

Portsmouth.—The Corporation have accepted the tender of Dick, Kerr, and Co., London and Edinburgh, at £202,409. 6s. 4d., for the permanent-way construction and underground feeders in connection with the equipment for electric traction of the tramways in the borough of Portsmouth, and extending to Cosham, Hants.

Bermondsey.—The following tenders for the supply and erection of cast-iron lamp columns, arc and incandescent lamps, switchings, and fittings have been submitted to the Electric Lighting Committee: Messrs. Oliver and Co., Plumstead, £2,848. 10s. 3d.; Johnson and Phillips, Old Charlton, £2,842. 8s. 9d.; Verity's, Covent Garden, £2,845; Crompton and Co., Mansion House-buildings, £2 595; Haydn, Harris, and Co., 11, Victoria-street, S.W., £3,292; Brockie-Pell Arc Lamp Company, £3,718.

Dartford.—The Urban District Council have received the following tenders for the erection of an electric light station at Dartford:

T. Martin, Dartford	£8,043
Leslie and Co., Kensington-square, W.	6 537
J. Lonsdale, Swanley Junction	5,935
Perry Bros., Cambridge Heath, N.E.	5,807
J. Smith and Sons, Norwood, S E.	5,619
H. Somerford and Son, Clapham, S.W. (accepted)	4 906

Brighton.—Eleven tenders have been received for the construction of tramroads and laying down wood paving in certain streets of the borough. The tenders are in two sections—viz.: (A) for the construction of the tramways and the laying of wood paving on the tracks with Jarrah wood, except where soft wood is necessary; (B) for the laying of wood paving on each side of certain of the tramway tracks. The tenders range in Section A from £68,217 to £87,013. 7s. 5d., and in Section B from £20,224 to £40,038, the quotations in the latter section varying according to the description of the wood. The totals for the two sections vary from £102,487. 14s. 5d. to £121,327. 3s. 5d. At last night's meeting of the Town Council it was recommended to accept the tender of Messrs. Macartney, McElroy, and Co., Limited, of Glasgow, to construct the permanent way of the tramways, including the paving of the tracks with Jarrah wood, except where soft wood is necessary (Section A), and to construct wood-paved carriageways on each side of, but excluding the tramway tracks, of Jarrah wood (Section B), in accordance with the specification prepared by the borough engineer and surveyor and the tramways engineer, the wood to be the quality of the sample submitted, the whole of the work to be completed on or before Aug. 31, 1901, for the sum of £102,487. 14s. 5d.

BUSINESS NOTES.

TRACTION.

Colchester.—The Town Council have sealed their application for a tramways provisional order.

Wolverhampton.—The Tramway Committee have decided that the space outside the tramway lines should be macadam or granite setts.

Newcastle.—The Corporation are negotiating with the Walker Council to run a tram service through Wallsend and Willington Quay districts.

Smethwick.—The Corporation have now agreed to grant a lease to the British Electric Traction Company of the tramways within the borough for 21 years.

Huddersfield.—Early in January a portion of the tramway service will be run by electric traction. The question of the Sunday running of cars will be considered shortly.

Esher.—The Urban District Council have declined to assent to the London United Tramways Company's application with regard to the proposed tramways so far as they might lie within the jurisdiction of the Council.

Ayr.—The Town Council have agreed to borrow £50,000 for electric tramways from the Prudential Assurance Company at 3½ per cent., the loan being repayable, principal and interest, in 80 equal half-yearly instalments of £1,166.

Glasgow.—The Corporation have passed a provisional order under which power is sought to make 10 extensions of the tramways, including lines to Renfrew, Govan, Rutherglen, and Cambuslang, the total distance being about 12 miles.

Keighley.—The Town Council at their last meeting discussed the question of purchasing the Keighley Tramway Company's lease. The line itself has for some time been the property of the Corporation. No public announcement was made of the result.

Sheffield.—The Tramways Committee have reported a profit of £12,562 for the half-year ended Sept. 29, of which £7,802 has been placed to reserve, leaving £4,760 to be placed to the accumulated net surplus. The profits since the Corporation took over the tramways shows a total of £64,000.

Bournemouth.—At the monthly meeting of the Town Council it was announced that the Poole and District Electric Traction Company had accepted the Council's offer of widening the road at Bargates or pay the Council the cost, providing in either case the cost did not exceed £500 The matter was referred to the Roads Committee, the surveyor to submit plans.

Hyde.—The Town Council have formally passed a resolution authorising the Corporation of the borough to promote a Bill in Parliament, in conjunction with the Corporations of Stalybridge, Mossley, and Dukinfield, for authority to construct and work electric tramways and to supply energy in the boroughs named. The above resolution has been confirmed at a subsequent ratepayers' meeting.

Sedgley.—At the last meeting of the Urban District Council letters were read from the British Electric Traction Company, stating that that company were just as anxious as the Council for the work of the scheme for electric trams to be proceeded with, and no unnecessary delay would take place with the construction of the line. Directly circumstances would permit, the work would be proceeded with.

Waterloo-with-Seaforth.—The Urban District Council last week received a communication from the Liverpool Corporation Tramways with reference to the proposal to construct a tramway along Seaforth road, and also a memorial from property owners, ratepayers, and residents of Seaforth protesting against the proposal, the consideration of which was deferred until the manager of the company had been interviewed.

Willington Quay.—Mr. Mertz and Mr. McClelland, engineers of the tramways company, have explained to the District Council that the laying of the proposed lines which would branch out from Wallsend, one going by the high road and the other by the riverside, will not necessitate the alteration of any roads or levels. The tramways would run past the large works, and at Willington Quay would run through the principal street.

Bolton.—The Corporation have passed the statutory resolution in regard to their Bill, under which works estimated to cost £350,000 are to be constructed. Out of that sum borrowing powers to the amount of £215,000 are asked for the cost of the new tramways and reconstruction of existing lines, and for the electric equipment of the new tramways a further sum of £15,000, the borrowed moneys to be repaid in 30 years.

Douglas.—The committee of the Tynwald Court recently discussed the question of providing facilities for conveying passengers along Ramsay Pier. Mr. Shaw showed that by an electric overhead wire a motor with two trailers could be put upon the pier, the whole to cost £850. The committee decided to recommend that Mr. Shaw's scheme should be accepted if the structure of the pier would stand the strain, and the enquiry was adjourned to Wednesday next at Douglas.

Ashton-under-Lyne.—The Town Council have resolved that application be made to the Board of Trade, under the Tramways Act, 1870, for sanction to borrow £26,570 for the purposes of the Ashton-under-Lyne Corporation Tramways Order, 1900; also that the Council adopt a memorial to the Board of Trade praying for a provisional order authorising the Corporation to construct, maintain, and work certain tramways in the township, parish, and borough of Ashton-under-Lyne, and to order the corporate seal to be affixed thereto.

Halifax.—Mr. A. P. Trotter on the 17th inst. inspected the newly-completed tramway extensions from King Cross to Tuel-lane Top, on the Hebden Bridge route, and from Boothtown to Catherine Slack, on the Queensbury route. As a result the section to Tuel-lane was opened for half-hourly service on Tuesday. With regard to the Catherine Slack section, the inspector preferred that the line should be inspected by the Board of Trade's permanent-way inspector before being opened for traffic, and the latter will visit Halifax for that purpose to-day.

Chester.—The question of the Chester tramways, upon which a poll of the citizens is to be taken during the first week in January, was the principal subject of discussion at the meeting of the Town Council. There appears to be considerable misapprehension on the part of the ratepayers as to the scheme. The Mayor said the extreme limit of the cost of the scheme, presuming all the powers to be exercised in the most expensive way, would be £150,000; but no particular scheme had as yet been adopted. It was decided that a plain statement of the facts of the case be issued to the public.

Richmond.—The report of the Tramways Committee, which was approved by the Town Council at their last meeting, dealt with the tramways proposed by the London United Tramways Company, and concluded as follows: "The committee do not at the present moment deem it necessary or desirable to submit any definite recommendation to the Council, except that the consent asked for be not accorded. The Bill will be deposited on or before the 21st inst., and they will then be in a position to consider its provisions in detail and submit recommendations as to any steps to be taken thereon."

Bradford.—The formal opening of the new electric tramway from Four Lane Ends, Bradford, to Thornton took place on the 18th inst. At a luncheon held subsequently at the Great Northern Hotel, Thornton, the chairman of the Tramways Committee (Councillor James Hill) said he considered that the opening of the Stanningley and Thornton lines would be the means of putting thousands a year into the pockets of the Bradford Tramways Company. When, however, the Corporation took over the private enterprise, both lines would prove a success, and they would be able to run right through to the city for 3d.

York.—The Corporation have agreed to purchase the tramways on the following terms—viz.: the price of the tramlines, setts,

Digitized by Google

land, and buildings to be £12,000; the price for the cars and other rolling-stock, horses, harness, tools, and effects, hay and other consumable stores to be ascertained by valuation on completion of the purchase; the purchase to be completed at the expiration of two years; pending completion the company to work the tramways on its own behalf, and to be entitled to the profits, and the Council to maintain and keep in repair the tramrails and roads. The resolution further authorised application to the Board of Trade for their consent to the purchase.

Surbiton.—At a general meeting of the local ratepayers' association last week resolutions were passed asking the Council to call a meeting of ratepayers and electors to consider whether trams should or should not be admitted to the district, and to receive a deputation on the subject. The Council, however, have decided that no useful purpose would be served by receiving a deputation at the present time. The Council have sealed the tramway company's agreement, which, we are informed, is very favourable to the company, as the Council is, we understand, to have the option to purchase the undertaking in 25 years' time at a valuation.

Cleethorpes.—At the last meeting of the Urban District Council it was agreed to ask the tramways company to place before the Council without prejudice all the contracts entered into by them for the erection and equipment of the power station, and then the Council would come to an early decision as to whether they would proceed with their electricity scheme, and serve an unconditional notice on the company to sell the site of the station and the station and plant. It was also carried that a portion of Grimsby-road, having been open more than 21 days, as specified in Clause 3 of the agreement to the Act of 1899, the Council require it to be reinstated within seven days for traffic, failing which steps be taken to carry into effect the terms of the agreement.

Leicester.—The Tramways Sub-Committee in their report recommend the adoption of the overhead trolley system of electric traction, with a central electric traction power station, to be situate on land adjoining the Lero refuse destructor in Belgrave-gate; further, that the continuous direct current system of generating plant be adopted, and designs and tenders, when required, be obtained from electric traction firms for boilers, engines, generators, switchboards, and all other electrical and mechanical equipment on a specification prepared with the advice of the consulting engineer; also that, when required, designs and tenders for overhead equipment, feeder cables, etc., be obtained under similar conditions; and that parliamentary powers be sought which should include the reconstruction and extension of the present tramways and the construction of a number of new lines over routes, most of which are covered by the existing 'bus services. Altogether the total length of the routes will be about 20 miles.

Walsall.—The Tramways Committee have agreed upon the lines to be laid down in connection with the authorised extension. The cost of construction and electrical equipment is from Park-street, along Wolverhampton-road, roughly estimated at £10,000 a mile. The committee have approved of the draft lease to the South Staffordshire Tramways (Lessee) Company, Limited, of the tramway lines from the borough boundary on the Wednesbury and Darlaston roads to the Brown Lion Inn at the Pleck for 21 years, and from the Brown Lion Inn to Bloxwich and Mellish road for three years from Jan. 1 next, in accordance with the terms of the agreement, dated Nov. 23, 1899, and scheduled to the Walsall Corporation Act, 1900, and they have sealed the conveyance from the South Staffordshire Tramways Company to the Corporation of the tramway undertaking in the borough, and to an assignment of the tramway depôt at Birchills, and also to the said lease. Various resolutions have been adopted to the effect that the repairing and maintaining of the tramways be added to the borough surveyor's department, and that a ganger and three men and the requisite plant be secured, and that the various lines agreed upon be constructed.

Cardiff.—In consequence of Mr. Ellis's report, it has been agreed that Mr. Harpur, the borough engineer, who will lay the tramway track, will meet Mr. Glenn, the engineer of the tramway company, to see if they can arrange matters so that the company's tracks, which are the lines in the centre of the town, may be got ready for electric traction when the Corporation acquire the lines in January, 1902. Work was commenced on Monday on the section—Cathedral-road to the docks—at Cowbridge-road end of Cathedral-road by a gang of 50 men. The street on either side of the track will be laid with wood blocks, and between the two sets of rails a new kind of composite block will be laid as an experiment. Similar work will be commenced shortly in Castle-road. Mr. A. Ellis has advised the Tramways Committee that they would have to consider the question of cars, seeing that the makers were so full of orders that it would take nearly a year to deliver. Mr. Ellis said they would want 120 cars—100 for actual running and 20 for standing by and emergencies. This will involve an expenditure of between £80,000 and £90,000. A resolution recommending that the committee visit certain towns to see the type of car now running, and manufacturers' sheds to see the class of material used, was carried.

British and Foreign Electrical Vehicle Co.—This Company has been registered with a share capital of £150 000, of which the vendors take 96,000 fully-paid £1 shares in part payment of the purchase consideration. The balance of 54 000 shares of £1 each is just now being issued. The Board is composed of Colonel J. F. Caldwell, J.P., and Messrs. Roger H. Fuller, Theodore G. Chambers, and Ernest W. Hart; and Sir Wm. H. Preece is the consulting engineer. The Company owns carriage depôts, works, and charging stations in Lambeth, Notting Hill-gate, Kensington, and Shoreditch, and has been formed to acquire the assets of the Leecoll Electric Battery Company, Limited, together with one-half share in the Leecoll patents in Victoria and New South Wales, France, Belgium, Italy, Hungary, and Spain, and in any other countries where it may hereafter be thought desirable to take out patents (with the exception of the United States and Canada, wherein patents have been granted; but this Company acquires no rights as to these countries) Patents have been applied for in Austria, Germany, Norway, Russia, and India. The British patents are owned by the Leecoll Electric Battery Company, Limited, who sell them to this Company, together with all their properties and contracts. From the description of the Leecoll accumulator in the prospectus, we understand that it gives 12 watt-hours per pound of cell during a five hours' discharge, and it is made on an original plan, a metallic coating being deposited on the negative when in the act of charging, and being stripped off when discharging, so that there is no active material to fall out of position, and no possible chance of buckling, the durability of the Leecoll cell is apparent. It is also stated that the cost of maintenance is extremely low, and that the cost of manufacture of the Leecoll battery is much less than that of lead plate cells, as no skilled or expensive labour is required. An interesting report on tests made by Sir William H. Preece over a period of four months is included in this document, which appears in another column. We are informed that the property acquired in Lambeth for £7,000 is the old electrical cab station, which cost originally from £30,000 to £40,000. It is a good sign that the vendors are taking all their interests in shares except in respect to properties.

Liverpool.—At the adjourned meeting of the Town Council last week the overcrowding of the tramways was discussed, and this brought to light a statement to the effect that, while when the tramways company had the tramways the cars were only licensed to carry a certain number of passengers, the present cars are not licensed to carry any certain number of passengers, and, therefore, there is no contravention of the law. This is more convenient to the authorities than the poor people who are overcrowded. In connection with this matter, we notice in the Liverpool daily Press letters complaining both of the overcrowding and of the one-class system on account of the writers having brought home from their journeys a number of involuntary contributions in the shape of unwelcome zoological specimens of various kinds. These people will hardly be satisfied at being told that their only remedy lays in trusting to their own legs, unless they can afford to hire a cab. The proceedings of the Tramways Committee, which were confirmed, contain a recommendation that the Council approve of a supplementary estimate of £15,000 on tramways ordinary account. It was explained by the gentleman who moved the acceptance of the minutes that this supplementary estimate was owing really to the increase of the traffic and passengers of the undertaking. At the beginning of the year they estimated the interest at £39,639, sinking fund and repayment of loans £40,096, and the working expenses £320,000 (the same as the year before). They found that during the year, owing to the rapid development of the system, the tramways had increased enormously. The receipts had increased over 15 per cent., the mileage about 19 per cent., and the passengers 27 per cent., so that it would be plain to the Council that with such increase of traffic the expenses must also increase. Therefore it was that this £15,000 was required. Of course the undertaking was providing for this. It was not going to be any burden upon the rates, and the committee hoped at the end of the year they would have a surplus, not a large one, he was sorry to say, but probably £5,000 or £6,000 over working expenses. This year they had had more expense than they were likely to have in the future, as they had horse cars, omnibuses, and electric cars all to provide for. By the end of the present year they would have done with horse traction, and at that moment they had done away with the whole of the horse cars, but had still omnibuses running. With only electric cars working they hoped to have a large profit at the end of next year. Facilities have now been provided for a continuous electric tramcar service from the centre of the city (South Castle-street) to the North Docks, *vid* Breck and Breckfield roads.

Southampton.—The Tramways Committee have decided to recommend that the resolution authorising the Electricity Committee to maintain the electrical equipment of the tramways be rescinded, and that the Tramways Committee be empowered to take full control of the working of the tramways and the maintenance of the equipment other than the supply of electric energy. At a subsequent meeting it was resolved that the electrical engineer be instructed to proceed with the specification for the extension works, taking the line through Canute-road. It was also decided that the Electricity Committee be informed that the Tramways Committee anticipate that 10 additional cars will be ready for use on the new tramways through Canute-road and St. Mary's-road to the Avenue in March next, and asked whether they will be prepared to supply the increased power required at that date. The assistant borough accountant submitted a return showing an income in excess of expenditure of £4,893. 18s. 2d. for the period commencing April 1 and ending on Sept. 30, 1900. In moving the adoption of the report, the Sheriff said that relative to the extension of the tramways through St. Mary's street, the committee thought it was advisable, in view of the criticisms of the public over the reconstruction of the old system, that there should be a sub-committee to look after the work, and one had been appointed. Concerning the additional cars, they were to go on the present routes. It must be patent to everyone that the committee found it utterly impossible to cater for the traffic between

Digitized by Google

five and six o'clock in the evening. They had all the cars out, and then they had not only the general traffic, but also the workmen to deal with. In wet weather the difficulty increased, because people objected to sit on damp seats, and thus a large number of customers was lost. They hoped to have the new cars ready in three months. The new cars for St. Mary's route would have garden seats, and would have a larger carrying capacity than the present ones. They would be of full size, there being no Bargate to deal with. The committee asked that six cars should receive the "never wet" sets, which had been tried with satisfactory results. With regard to the profits for the six months ending September, the sheriff said they made £4,000 in the previous half-year, and the Council had received a similar amount from the committee for the present half-year, making a total of £8,000 during the present rate. But the committee felt that that was all the Council must expect for this year. They would have more money in hand, but they had decided to build up a reserve fund, and one for depreciation, so they asked the Council to be satisfied with what had been given them on this occasion. The report was adopted.

LIGHTING AND GENERAL.

Lichfield.—The City Council have sealed their application for an electric lighting provisional order.

Ince.—The Council are obtaining a report on electric lighting from Messrs. Lacey, Clirehugh, and Sillar.

Aspull.—Messrs. Lacey, Clirehugh, and Sillar are preparing a report on electric lighting for the Council.

Ayr.—The Town Council have agreed to borrow a further sum of £25,000 for electric lighting extensions.

Warwick.—The Town Council have confirmed their resolution to apply for a provisional order for electric lighting.

Nairn.—A scheme of electric lighting for the burgh, proposed by Mr. Purves, Edinburgh, is being considered by the Lighting Committee.

South Shields.—All the principal thoroughfares in the town, and many of the residential streets, are now illuminated with the electric light.

Barnard Castle.—The Urban District Council are taking no action with regard to the Cleveland and Durham Electric Power Company's Bill.

Chelsea Electricity Supply Co.—The transfer books of the debenture stock will be closed until Dec. 31 for the preparation of interest warrants.

Upholland.—The District Council appear to be favourable to the Lancashire Electric Power Company's scheme for supplying electric energy in bulk.

Larne.—The Urban District Council have just passed plans submitted by Larne Electric Company for laying down cable and for placing transformers.

Huddersfield.—Application has now been made to the Local Government Board for a 25 years' license to provide a local municipal telephone service.

Tonbridge.—Mr. R. Hammond's electric lighting scheme has been adopted, and application will shortly be made for sanction to a loan of £20 000 for that purpose.

Stoke-on-Trent.—The Local Government Board have agreed to extend the term of repayment for the electric lighting loan of £9,900 for the workhouse from 15 to 20 years.

Improved Electric Glow Lamp Co.—We are informed by this Company that they are taking up the sole and exclusive rights of the Hammond joint boxes, recently noticed by us.

Hebburn.—The Electric Committee are making enquiries of the various electrical power companies to ascertain the conditions upon which the companies can supply energy for all purposes.

Bacup.—A deputation of the Town Council has been appointed to wait on Mr. Pelham, at the Board of Trade office, for the purpose of obtaining an extension of the electric lighting order.

King's Lynn.—The Electric Lighting Committee have been instructed to enquire and report as to the powers and means of extending public lighting to the courts and yards of the borough.

Nuneaton.—The Council have approved the plans of the proposed new buildings at the electric works as prepared by the surveyor, and tenders will now be advertised for carrying out the works.

Salford.—The Tramways Committee will recommend the Council at its next meeting to appoint Mr. E. Hatton, at present tramways engineer, as both tramways engineer and general manager of the new electric tramways system.

Battersea.—Application is to be made to the London County Council for sanction to the loan of £10,600 in respect of additional mains, etc., which it has been decided from time to time to provide in connection with the electric lighting of the borough.

Dublin.—Fifteen members of the Electric Lighting Committee, including the Lord Mayor, have been surcharged with payments made to effect necessary alterations in the electric light supply to private consumers, amounting in the aggregate to £2 000.

Share Market.—There was a little more movement in electric shares during the past week. Sales were recorded in Bromptons, British Electric Traction, City, Westminster, St. James's, Edmondson preference, Metropolitans, and in British Columbian Electric Railway.

Personal.—Mr. J. Douglas Allan has been appointed junior assistant for distribution at the Leith Corporation electricity works.—Mr. Edward Unsworth, of 8, Greenhill-street, Greenheys, Manchester, has been appointed agent for Lancashire for Mr. A. P. Lundberg, M.I.E.E.

Hunstanton.—Mr. Stevenson's report to the Urban District Council shows that the cost of providing the electric light in the Council's district would be about £4,500, and if Old Hunstanton were included there would be £500 extra. The Council have agreed to apply for a provisional order.

Burton.—At the Town Council meeting last week a return was presented stating that the quantity of electric light sold in Board of Trade units during the past month was 26,955, showing an increase of 4,291. It was resolved that the Council undertake the letting out of electric motors on the hire-purchase system.

Cardiff.—The extension of electric mains in Newport-road is to be deferred on account of the change to the continuous-current system, which is to be made as soon as possible. The recommendations in Mr. Ellis's recent report as to concentrating the plant for lighting and tramways in one place at Roath have been accepted, and Mr. Ellis is to report upon the amount of plant required.

Manchester.—At the City Council meeting on Wednesday it was decided to appoint Prof. Kennedy electrical expert, on the terms that he shall receive either 4 per cent. upon all works executed by him estimated at £400,000, or an inclusive sum of £15,000 in half yearly payments. This sum does not include the architectural work of the shell of the building at Stuart-street, which will be prepared by and at the cost of the Electricity Committee.

Stroud.—Sir William Marling presided at a meeting of the Chamber of Commerce on the 19th inst. The chief business was to consider the rates charged by the National Telephone Company, and in the course of the discussion Mr. W. G. Clissold said the National Telephone Company had been the greatest hindrance to the extension of telephonic communication. Sir William Marling undertook to draw up a memorandum on the subject to be submitted to the Associated Chambers of Commerce.

Fire.—We regret to learn that on Saturday Messrs. Hooper's telegraph, cable, and rubber works at Millwall were destroyed by fire. Some idea of the extent of these premises may be obtained by the fact that they range about 200ft. long and 100ft. wide. Over 200 men have been thrown out of employment as a result of the disaster. It is reported that the cause of the outbreak is at present unexplained. The fire broke out in a building right in the centre of the works, where spun-yarn seizings, hemp rope, and guttapercha were stored.

Appointments Vacant.—The Electric Light Committee of Salford invite applications for the post of an electrical engineer at £700 per annum.—The Corporation of Southend-on-Sea require an electrical engineering assistant. Full particulars of these vacancies appear in our advertisement columns. The Lancaster Town Council have decided to advertise for an electrical engineer able to take charge of the electric tramways as well as the electric lighting. We have referred elsewhere to the post of tramway engineer to the London County Council (£1,000) shortly to be advertised. Application for the post of a foreman, to reside at, and take charge of the machinery and staff of, the generating station in connection with the electric light installation for the Victoria embankment and Westminster Bridge will also be advertised for shortly.

Manchester Telephones.—The City Council on Wednesday agreed that the consideration of the question as to whether it should reaffirm its decision of April 14, 1897, in regard to telephones, should be adjourned till the February meeting, and that the Telephone Committee should be instructed to confer with the Salford and other urban authorities within the Manchester telephone area on the subject of telephony and report to the Council at a future meeting. Our readers may recollect that the resolution referred to expressed approval of the objects of a proposed independent competing company, subject to terms and conditions being arranged to the satisfaction of the Corporation, and reserving to the Corporation a status to communicate with and be heard before the Postmaster-General or other Government authority in reference to the subject, and as to the conditions of any license affecting the city of Manchester.

Stock Exchange.—The Stock Exchange Committee have appointed Jan. 3 a special settling day for City of London Electric Lighting Company's provisional certificates (60 per cent. paid) for 200,000 4½ per cent. second debenture stock; Mount Chalmers Copper Mines 4,053 7 per cent. cumulative preference shares of £1 each, fully paid, Nos. 1 to 917 and 20,218 to 23,353; and 10,000 ordinary shares of £1 each, fully paid, Nos. 50,001 to 56,000 and 71,001 to 75,000; and Notting Hill Electric Lighting Company's further issue of 2,200 ordinary shares of £10 each, fully paid, Nos. 10,001 to 12 200. The undermentioned securities are to be quoted in the official list: Charing Cross and Strand Electricity Supply Corporation's further issue of 30,000 4½ per cent. cumulative preference shares of £5 each, fully paid, Nos. 20 001 to 50,000; and City of London Electric Lighting Company's provisional certificates (60 per cent. paid) for £200,000 4½ per cent. second debenture stock. Applications have been made to the Stock Exchange Committee to appoint a special settling day in Kalgoorlie Electric Power and Lighting Corporation's 150 000 6 per cent. cumulative preferred shares of £1 each, 10s. paid. Nos. 1 to 150,000; Marconi's Wireless Telegraph Company's 77 083 shares of £1 each, fully paid, Nos. 1 to 40,000 and 100,001 to 137 083, and 60 000 vendors' shares of £1 each, fully paid, Nos. 40,001 to 100,000; and Motor Manufacturing Company's 246,432 shares of £1 each, fully paid, Nos. 1 to 246,432.

Digitized by Google

Ilford.—The Surveyor reported at the last meeting of the Urban District Council that the electric generating station works were progressing satisfactorily. The report of a sub-committee who had visited Kingston-on-Thames to inspect the incandescent lamps in use there, and who now recommended the Council to adopt the same, was agreed to.

Whitehaven.—The Council have decided to apply to the Local Government Board for sanction to borrow £10,000 for the purpose of carrying out the works recommended by the consulting engineers, along with the contemplated extensions to public and private mains. A detailed estimate of the cost of the proposed works has been asked for.

Alloa.—The Burgh Commissioners will make a commencement with public lighting by placing eight arc lamps in various streets. The original scheme proposed by Mr. Spence included 32 lamps, and if the trial proves successful the number of lamps will be increased. Sanction has been obtained to the borrowing of £12,000 in connection with the Alloa electric lighting order.

Walsall.—The Electric Lighting Committee are unable to accede to the request that they should extend the existing main in Bradford street along Wednesbury-road so as to supply electric light to the Wednesbury-road Congregational Church, having regard to the probable small consumption of current. The total number of consumers supplied on Nov. 30 last was 169.

Pudsey.—A petition has been presented to the Town Council by the Independent Labour party against the granting of parliamentary powers to the Electric Power Distribution Syndicate on the ground that a combination of the local authorities could do the work more effectively. The Council are taking steps to prevent any company or any person coming within the township for the purpose.

Swadlincote.—A letter from the Board of Trade was read at the last meeting of the Urban District Council enquiring whether the Council had proceeded to carry out the obligations under the electric lighting order, and elicited that the clerk had been instructed to reply that no steps had been taken, and that the time already granted should be extended for carrying out the terms of the order.

Bermondsey.—The new Borough Council have come to the very sensible conclusion to approach the Board of Trade with a view to secure the insertion in a Bill that authority proposes to introduce in Parliament in favour of making electric lighting areas coterminous with the new borough areas, provision to extend the Bermondsey electric lighting order over the whole area of the Bermondsey borough.

Rochester.—The Town Council have an offer to purchase so much of the undertaking of the Rochester, Chatham, and District Electric Lighting Company as is within the city. Mr. F. Charles Raphael has been asked to advise the Corporation as to the value of the present distributing system within the city, and the valuation of the proportion of the provisional order will be considered after this has been done.

Heywood.—At the last monthly meeting of the Town Council it was resolved to apply to the Local Government Board to sanction the appropriation of a piece of land adjoining Egerton road for the purpose of constructing electric supply works thereon. It was also resolved that a conference of local authorities interested in the acquisition of the Bury, Rochdale, and Oldham Tramway Company, Limited, should be convened.

Bristol.—The Electric Committee have asked Mr. Williams, architect, to report whether he thought the plans prepared for the Avondale works were such that he could safely assume the responsibility of carrying out the works, and, if so, whether he would be willing to prepare a specification, give an estimate of the cost, and state a probable date when he thought the works would be completed. Various short extensions of the alternating-current mains have just been authorised.

St. Austell.—The Urban District Council have formally consented to the application of the St. Austell and District Electric Light and Power Company, Limited, for a provisional order under the Electric Lighting Acts, 1882-1899, in substitution for the order now subsisting and known as the St. Austell Electric Lighting Order, 1894; and the Council waive their powers of purchase thereunder, and concur in taking such steps as may be necessary to obtain the revocation of the order of 1894.

Lytham.—The Urban District Council have obtained a report from their consulting electrical engineer, whom they had asked if he could possibly see any means of reducing the estimate of lighting Lytham. He proposes by cutting out street lighting, to bring down the price of the current to that of gas. Taking 18 lights as the average number per house, it would only require 250 houses to cover all expenses. The committee have agreed to talk the matter over with the engineer and report to the Council.

Stoke Newington.—The Electric Lighting Committee recommend the Council that any provisional order that would confer power on any private person or body to supply electricity in the borough of Stoke Newington, otherwise than by agreement with the Borough Council, should be opposed. The chairman of the General Purposes Committee is to be added to this committee. Enquiries are to be made as to the probable consumption of electricity by private consumers in this borough in the event of such supply being furnished by the Council.

Wallsend.—Regarding a communication sent by the District Council to the Walker and Wallsend Gas Company concerning the new electric mains, and pointing out that the authority would not be responsible for any damage done to the mains because of their contiguity to the sewers, a reply from the company was read at the last meeting of the Council stating that the mains had been lawfully laid, and anyone who damaged them would be liable. It was decided that a letter be sent to the company intimating that the Council had resolved to defend their position.

B.E.T. Athletic Club.—The athletic club attached to the British Electric Traction Company recently held its second general meeting, the chair being taken by Mr. J. Devonshire, who gave a short *résumé* of the summer experiences of the club. He stated that the ground at Shepherd's Bush was now being used for football, and that the team had won four matches out of the first five played. On Friday, the 14th, the club gave a very successful smoking concert at Anderton's Hotel. The concert was well attended, and the organisers provided an excellent and varied programme.

Banbury.—The Electrical Power Distribution Company, Limited, are transferring their order, with the consent of the Corporation, to a subsidiary company which has been formed under the name of the Banbury and District Electric Supply Company, Limited. The charges for light have been fixed at 7d. per unit up to 100 hours as the maximum demand, and for any further quantity supplied 2½d. per unit. The charge for energy separately metered for power is the same, with the exception that 2d. is substituted for 2½d. The undertakers propose to commence their operations in the borough at a very early date.

Islington.—At the meeting to-day the following report from the Provisional Finance Committee is to be considered: "We have had under consideration a reference from the Electric Lighting Committee approving of a proposal by the late Vestry for the provision of additional water storage by the erection of a water tower and tanks, and of a switch gallery along the engine-house, and other works at the electric lighting station in Eden grove at a total estimated cost of £7,496. We have ascertained that sanction to borrow to the extent of £6,606 was obtained by the late Vestry from the London County Council. We adopt this amount (£6,606) as our estimate of the cost of the proposed works which are covered by the sanction in question, and we recommend that the Electric Lighting Committee be authorised to carry out the works to the extent of that sanction."

Darlington.—The new electric lighting works in Haughton-road were opened on Monday. The system adopted is a three-wire continuous current of 460 volts. The works have been in progress for some months, and it is intended to light the principal thoroughfares, while there has been a large application from shops, works, and other customers. The street arc lamps are not yet in operation, but are in course of erection. The switching-on of the light was undertaken by Alderman Barron, the chairman of the Corporation Gasworks and Electric Lighting Committee, who explained that it was considered desirable at the earliest moment to give tradesmen and others who were ready with their wiring the advantage of the light. The works are capable of supplying about 7,000 8-c.p. lamps, and will be a great acquisition to the town. The total cost comes to about £25,000.

Aberdeen.—At their last meeting the Gas and Electric Committee considered the plans for the proposed new electricity station at Dee Village, and agreed meantime to defer further consideration of them until the Tramways Committee should have considered the accommodation which would be required by them at the station for repair purposes. There are eight plans, and it is proposed to erect buildings of a very substantial character. Provision is made for a battery-room, with offices; testing-room, with motor and lamp store above; for workshops, with stores above; for weigher and checker, workmen's mess-room, engine-room, boiler-house, economiser-house with water-tank above, a hot-water well underground, and a chimney stalk of a most elaborate and ornamental nature. The work of laying the electric subway which is to contain the cables from the new Dee Village electric station will also be carried out in connection with the construction of the sewer in Crown street, the subway so far running along the top of the sewer.

Taunton.—The Electric Lighting Committee in their last report recommended the Council to adopt the following scale of charges to be paid for the hire of motors from the Corporation: ½ b.h.p., 100 volts £2. 200 volts £2. 5s. per annum; 1 b.h.p., 100 volts £3, 200 volts £3. 5s.; 2 b.h.p., 200 volts, £4; 3 b.h.p., 200 volts, £5; 4 b.h.p., 200 volts, £6; 6 b.h.p, 200 volts, £8; 9 b.h.p., 200 volts, £9; and 12 b.h.p., 200 volts, £10. 10s. per annum. In the event of a hirer wishing to purchase a motor, he will be allowed to do so on payment of the cost of the motor less half the rent already paid for hire. The agreement with the Free Wiring Company has been terminated, and the committee have under consideration a scheme for free wiring by the Council similar to those adopted by other corporations. With regard to the recent breakdown of the Staplegrove cable, we learn that the accident was due to the fact that a larger number of connections have been made than were anticipated when the cable was laid down, and thus the cable was insufficient to meet the demand.

Wakefield.—At the last meeting of the Town Council, a considerable discussion arose as to the best means of street-lighting. Two committees, who apparently have jurisdiction over the same area, submitted their minutes. The principal resolution of the Electric Lighting Committee, whose minutes were adopted, embraced an instruction to the electrical engineer to prepare the specifications, etc., for the provision of a high-speed plant (recommended by the sub-committee because the same would run better in parallel than a slow-speed set) for the electric lighting works; that the town clerk advertise for tenders for supplying the same; and that Councillors Wigham (chairman), Powell (vice-chairman), Childe, Harrison, and W. H. Smith form a sub-committee to open

Digitized by Google

the tenders. The Street-Lighting Committee's minutes dealt with improved lighting in the Alverthorpe Ward in particular and the city in general. The committee recommended the erection of incandescent lamps of varied candle-power by the Wakefield Gas Company. During the discussion it was asked whether the Lighting Committee had ascertained the amount annually required for renewals in the matter of incandescent lighting, but no answer was given. Finally it was agreed that the minutes be adopted with the exception of that part dealing with the additional lighting of the old portion of Wakefield, which be referred back to the committee for reconsideration.

Leeds.—It is expected that by next Easter one of the 1,500-h.p. engines for the electric power station will be ready. Other two similar engines are to follow, and when these are set up the Corporation will be able to deal with 300 electric cars, instead of the modest 82 which the present 1,300-h.p. and 400-h.p. engines feed. The foundation for the new machinery is now being laid. By Christmas next year it is possible, therefore, that there will be no fewer than 300 motors in the streets of Leeds. Of course, special traffic arrangements are to be made to deal with this enormous addition to the already congested central thoroughfares of the city. The Town Council, in fact, has recently been considering these arrangements. According to Mr. Spaven, the traffic manager, all the electric tram routes are under carred. The Town Council at its meeting on Tuesday evening instructed Messrs. Hopkinson and Talbot to prepare specifications for the equipment of the Armley, Wortley, and Stanningley routes, which will complete the electrical tramway installation in the city. The committee also examined a new fare-collecting apparatus. The salary of Mr. Burbridge, the electrical tramway engineer, has been increased from £400 to £600. Mr. Burbridge is a comparatively young man, and has been in the service of the Leeds Corporation for about three years. At a meeting of the Lighting Committee of the Corporation it was decided to extend the electric lighting mains from Whitehall road along Spence-lane, Wellington-road, and Tong-road, as far as Wesley-road, Armley.

Swansea.—The proposed agreement between the Corporation and the National Electric Wiring Company in connection with the electric lighting scheme provides that the company shall, when required by the Corporation, provide and fix the necessary wires and fittings for using electricity for lighting purposes on the premises of any consumer, with certain exceptions. The company are to be responsible for all proper legal claim for damage or injury done by them or their agents to any premises wired or fitted by them, while the Corporation will render to the company quarterly accounts indicating the amount of electrical energy supplied to the premises to which wires and fittings have been supplied, and the amount received by the Corporation in respect thereof, "and until such wires and fittings have been paid for as hereinafter provided, the Corporation will pay to the company for the use of the installation 1d. per Board of Trade unit for the first period on a sliding scale, during which the Corporation would charge the consumer their maximum price for energy supplied, and will pay the company an amount proportionately below 1d. per unit *pro rata* with the reduction in charge made by the Corporation for periods under the sliding scale in which the consumer would be charged less than the maximum price, provided that the price per Board of Trade unit shall in no case be less than ½d., and provided that the minimum payment to the company in any year shall be 1s. 4d. per lamp installed." The Corporation, it is further provided, shall not make any payment in cases of defaulting consumers, and the sliding scale (as already reported in these columns) gives every consumer the option during the first four years of purchasing the wires and fittings at the original cost price, plus 25 per cent., and less 1½ per cent. per annum for depreciation, and so on to 22½ per cent. and 20 per cent. for the fifth and subsequent years, and such original cost shall include the costs of labour, materials, superintendence, and all expenses of general management." The Corporation also have the power of compounding for the purchase of the whole of the fittings, etc., and in both events "the company shall render to the Corporation an account of the prime cost to the company of such wires and fittings." In other clauses, a consumer, by paying the difference in cost, may have special fittings, while the company "shall not be liable for any repairs to or maintenance of the wires and fittings, all of which, including the renewal of the lamps, shall be done by the consumer at his own expense." This does not refer to defects in materials or workmanship during the first year. The agreement is terminable by six months' notice on either side.

London County Council.—At Tuesday's meeting of the Council it was agreed to lend the Battersea Borough Council £20,000 for electric lighting purposes, and the Woolwich Borough Council £20,000 for electric lighting and dust destructor works. The Highway Committee's recommendation that an electrical engineer be appointed, at a salary of £1,000, was adopted. We deal with this question in another column. The report of the Highways Committee also contained the following recommendation: "That, notwithstanding the provisions of the agreement entered into by the Council with Dr. A. B. W. Kennedy in accordance with the resolution of the Council of Oct. 10, 1899, the Council do accept the offer of Dr. Kennedy to act as electrical engineer for the reconstruction, for electrical traction, of the tramways between (*a*) Westminster Bridge and Tooting; (*b*) Kennington-gate and Blackfriars; and (*c*) St. George's-circus and Waterloo-road. That he be paid in respect of his services a commission equal to 4 per cent. on the cost of the reconstruction of the said tramways, and to 1 per cent. on the cost of buildings, and that it be referred to the solicitor to complete the arrangement." The application of the National Telephone Company for permission to lay a short length of wires underground from the corner of St. John's-road and John's-hill, Clapham Junction, to new premises of the company at 248, Lavender-hill, the object of the work being to enable it to remove its exchange from the present position in Battersea Park-road to the new premises, will be agreed to provided that the company before commencing the work obtain the consent of the Postmaster-General thereto. The Council will also grant permission to the Exchange Telegraph Company to lay two 3in. pipes underground across the Victoria-embankment upon the usual conditions. The following notices under Electric Lighting Acts and Orders were agreed to: City of London Electric Lighting Company to lay mains along a portion of Blackfriars-road; County of London and Brush Provincial Electric Light Company power, etc., to lay low-tension mains to and at Red Lion Market, and low-tension mains along both sides of Torrington street and square; also several notices from the Metropolitan Electric Supply Company to lay high-tension mains along portions of Wells-road, Albert-road, Lancaster-terrace, and along a portion of Cavendish-road, also to lay low-tension mains along Carey-street and Bell-yard. The Council have also received notices under the several orders granted to the Hammersmith, Stepney, and Lambeth local authorities (the latter being in hands of the South London Electric Lighting Company), under which the Council have no power to disapprove or approve.

PHYSICAL SOCIETY.

At the ordinary meeting held in the physical laboratory of the Royal College of Science (by invitation of Prof. Rücker) on Dec. 14, 1900, a paper "**On Electric Inertia and the Inertia of Electric Convection,**" was read by **Prof. A. Schuster.** Calculations of self-induction are based on the assumption that the currents which traverse a conductor fill it continuously, the flow being treated as that of an incompressible liquid. The assumption is generally recognised not to hold in the case of electrolytes where electricity is conveyed by a number of irregularly distributed ions. In the immediate neighbourhood of such an ion the magnetic field is many times greater than that calculated on the supposition of continuous distribution, and hence the total magnetic energy is underestimated. What is universally recognised in the case of electrolytes must also be conceded when the current is conveyed by a gas, and the idea is gaining ground that even in solid conductors the current consists of positive and negative electrons moving with different velocities. It is the object of the paper to calculate the additional terms which become necessary for the evaluation of self-induction, and to discuss the possible cases in which the corrections may effect experimental results. The mathematical investigation shows that it is necessary to add a correcting term containing a quantity which may conveniently be called electric inertia. The author has calculated the numerical value of this quantity in the case of a solid conductor, and finds it to be about 2×10^{-13} C.G.S. units. It is of the dimensions of a surface. The experiments of Hertz have proved that if electric inertia exists it must be less than 18×10^{-6}. In the case of liquids and gases, the electric inertia of the moving ions becomes much more important, and the calculation of self-induction by the ordinary processes gives erroneous results. The introduction of a term representing inertia alters the general equations of electric motion, and the author has applied his modified theory to Leyden jar discharges, the electrodeless discharges of J. J. Thomson, and the electromagnetic theory of light. In the case of electrodeless discharges in a vacuous globe, it is suggested that the absorption of energy may not only be due to the conductivity of the gas, but also to the inertia which it possesses.

A paper "**On Magnetic Precession**" was then read by the same author. The most delicate method of investigating the influence of electric inertia is based on the E.M.F.'s introduced by the motion of conductors carrying electric currents. If electricity behaves like a body possessing inertia, the rotation of a body through which currents pass should affect the flow of these currents in the same manner as the earth's rotation affects the direction of currents of air. If the earth's magnetism is due to electric currents, it is interesting to see if the affects of inertia can explain the secular variation. The investigation shows that a magnetic precession of the character of the secular variation would be produced, but that the precession would be very much slower than the variations actually observed. The subject is worked out mathematically, dealing first with the case of currents in a spherical shell and then extending the result to the case of a solid sphere. The calculated period of a cycle comes out as 7×10^{14} years If the currents are confined to a thin slice of the earth, the time would be reduced to about 14×10^{6} years. To produce the actual period of the secular change, the current sheet would have to be of molecular dimensions. This suggests the possibility of the phenomenon of secular variation being rather of a molecular than a molar character.

Prof. Rucker congratulated the author upon his attempt to solve the problem of terrestrial magnetism, and expressed the hope that further calculation would throw more light upon this difficult subject.

Mr. Blakesley asked if the time of the secular variation would be altered if the interior of the earth were liquid or solid?

The **Chairman** observed that the precession was rapid in the case of a thin layer of gas, and mentioned J. J. Thomson's notion

Digitized by Google

that the electrons were thrown off by centrifugal force and formed a molecular layer. Hertz, in his experiments on electricity, had looked for material inertia besides electromagnetic inertia. In the present theory the distinction disappears, and there is only one inertia, and that electromagnetic.

Prof. Ayrton said if the two forms of inertia were electromagnetic, he would like to know why in detecting the second form it was necessary to associate it with an absorption of energy, as in the case of an electrodeless discharge. In the case of ordinary self-induction there is no absorption of energy, and if there is absorption in the second form, and if they are both electromagnetic, he would like to know the difference between the two.

Prof. Schuster, replying to Mr. Blakesley, said that if the interior of the earth were treated as liquid the period of the cycle would be about 100 times less. In reply to Prof. Ayrton, he said he had only cited one experiment to show that a phenomenon explained by the gas being a good conductor could also be explained by its electric inertia. It was impossible to say in general whether self-induction caused an absorption of energy or not.

Prof. A. W. Rucker read a paper "**On the Magnetic Field Produced by Electric Tramways.**" Taking the case of a tramway in which the current flows along a trolley wire from the power-house and returns partly through the rails and partly as earth currents, the author has shown that the vertical disturbing force at any point is due to the currents in the feeders and rails, and that the earth currents affect the horizontal force only. Experiment shows that it is chiefly the vertical force instruments which are affected by the establishment of an electric railway, and since this disturbance is due to the wires and rails, it is impossible for an observatory to be protected by rivers or other natural features of the district. A preliminary investigation is based on the assumption that the trolley wires and rails are insulated conductors, and that a fraction of the whole current returns along the rails to the generator. The effect of the railway at a distant point is due to the difference of the current in the trolley wire and the hypothetical uniform rail current, the effect of which at the point considered is equivalent to the actual rail current, which varies from point to point. It is thus shown that the disturbance increases with the length of the tramway, and for a tramway of given length the disturbance is a maximum at points on a line perpendicular to and bisecting it. Experiments made at Stockton on the magnitude of the disturbing force gave, with the vertical force instrument, a leakage of 16·3 per cent., and with the horizontal force instrument a leakage of 15·9 per cent., a fairly close agreement. The assumption that the terminals of the line are above and below the average potential of the earth by the same amount respectively, and that the leakage at any point is proportional to the potential difference between the rail and the earth, leads to the ordinary theory of a Fourier bar. This more accurate assumption has been developed and applied to the results obtained at Stockton. The leakage as calculated from the amperes and volts comes out as 20 per cent. The calculation of the disturbing vertical force gives $10{\cdot}5 \times 10^{-5}$ C.G.S. units, which is in fair agreement with the value 7×10^{-5} actually observed. In conclusion, it is pointed out that for practical purposes it is sufficient to deal with the average return current through the rails, the formulæ for which are quite simple.

Dr. R. T. Glazebrook read some "**Notes on the Practical Application of the Theory of Magnetic Disturbances by Earth Currents.**" In this paper the author has thrown the extended formula obtained by Prof. Rücker in the previous paper into a workable form, and has tabulated numbers which show at what distances the disturbances are negligible for tramways of different lengths.

Prof. R. Threlfall exhibited a "**Quartz-Thread Gravity Balance.**" Prof. Threlfall gave a short description of this instrument, which has been described in full elsewhere. He drew attention particularly to its accuracy and portability.

Mr. Simpson asked how far the fibre had been calibrated, and if the instrument would be reliable at the freezing point of mercury.

Dr. Glazebrook asked how far the instrument was suitable for antarctic expedition work. He drew attention to the difficulty of calibrating a new fibre should one get broken in the field.

Mr. Appleyard suggested the use of a bath kept at constant temperature with a thermostat.

Prof. S. P. Thompson suggested a special meeting to discuss the physics of the antarctic expedition.

Prof. Threlfall said that there was no difficulty in measuring the relation between temperature and coefficient of stiffness down to very low temperatures. A more difficult matter is the coefficient of temperature of the instrument. Shrinkage of the instrument as a whole affects both the fibre and the spring which supports it. The difficult of a broken fibre in the field can be got over by taking two or three instruments. Working with a thermostat is useful in a laboratory, but decreases the portability in exploration work.

Mr. Watson then exhibited a set of half-seconds pendulums. In these pendulums special attention is paid to the stability of the support. They are covered by a hood from which the air can be exhausted, so that the logarithmic decrement is diminished. The motion of the pendulums is shown by rays of light reflected from right-angled prisms attached to them, and the period of oscillation is determined by the method of coincidences. For this purpose an accurate astronomical clock is used, and observations are made continuously between two time signals. An accuracy of one part in a million is attainable.

In reply to **Prof. Threlfall, Mr. Watson** said that the knife-edges were on the pendulums, and not on the supports.

The society then adjourned until Jan. 25, 1901.

PROVISIONAL PATENTS, 1900.

DECEMBER 10.

22433. Improvements in metallic conduits for electric light cables and the like. Lawrence Maxwell Waterhouse and the Simplex Steel Conduit Company, Limited, 34, Castle street, Liverpool.

22434. Improvements in metallic conduits for electric light cables and the like. Lawrence Maxwell Waterhouse and the Simplex Steel Conduit Company, Limited, 34, Castle-street, Liverpool.

22352. Improvements in automatic potential regulators for dynamos. Newnham Browne, 73, Cheapside, London. (The Tirrill Regulator Company, United States.)

22476. Improvements in staples for electric wires. Hermann August Litz, 72, Cannon-street, London.

22484. Improvements in prepayment electricity meters. Ernest Schattner, 55, Chancery-lane, London.

DECEMBER 11.

22503 Long quick-break spring contact switch. Fred Atkinson and William Atkinson, Brook-Lynne, Roundhay-road, Leeds.

22508. Electrical resistance switch. James Cusworth, 41, Park-road, Newcastle-on-Tyne.

22515 An automatic telling contact for electric bells. Albert Browne Mudie, Cambridge-street Works, Birmingham.

22542. Improvements in means for supporting electric lamps. August Richter, 111, Hatton-garden, London.

22546. Improvements in electrical interrupters for gas-engines. Theodor Bergmann, 72, Cannon-street, London. (Complete specification.)

22572. Improvements in or relating to electrostatic machines. Karl Schall, 8, Quality-court, Chancery-lane, London. (Reiniger, Gebbert, and Schall, Germany.) (Complete specification.)

22584. An electric furnace with two bedplates. Charles Albert Keller, 322, High Holborn, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, May 21, 1900, being date of application in France.) (Complete specification.)

22585. Improvements in flexible supporting structures for electric lamps. William Farley Brewster, 322, High Holborn, London. (Complete specification.)

22591. Improvements in magnetic ore separators. Charles Albert Barnard, 6, Lord-street, Liverpool. (Complete specification.)

22599. Improvements in the manufacture of incandescence bodies for electric glow lamps. Alexander Just and Robert Falk, 46, Lincoln's-inn-fields, London.

22605. Improvements in and relating to plate holders for electric accumulators. Theodor Müller, 18, Buckingham-street, Strand, London. (Complete specification.)

22606. A process for chemically consolidating the active material of electric accumulators. Theodor Müller, 18, Buckingham street, Strand, London. (Complete specification.)

22607. Improvements in or relating to electric accumulator cells. Theodor Müller, 18, Buckingham-street, Strand, London. (Complete specification.)

DECEMBER 12.

22628. Improvements in electric or electro-pneumatic organs. Robert Hope Jones, 44, Grove-avenue, Norwich.

22662. Process for the manufacture and repair of electrical glow lamps. Fritz Blau, Alexander Scharf, Isidor Löti, Sandor Löti, and Rudolf Latzko, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

22665. Improvements in trolleys for electrical locomotives, tramcars, or the like. Edward James Faraday, 34, Castle-street, Liverpool.

22678. Improved means applicable for use in transmitting energy to electrically-propelled trains or tramcars. Sidney Howe Short, Clun House, Surrey-street, Strand, London.

22679. Improved means applicable for use in operating and controlling electrically-propelled trains or tramcars. Sidney Howe Short, Clun House, Surrey-street, Strand, London.

22680 Improvements in electric current switching apparatus. Reginald Page Wilson, Clun House, Surrey-street, Strand, London.

22690. Improvements relating to electrical traction. Kenric James McMullen and John Alexander McMullen, 323, High Holborn, London.

22693. Process of extracting and reducing metals by electrolysis. Hans Albert Frasch, 40, Chancery-lane, London. (Complete specification.)

22699. Process of recovering and separating metals from their ores and concentrates thereof. Hans Albert Frasch, 40, Chancery-lane, London. (Complete specification.)

NOTES.

Street-Lighting in Paris.—We understand that street-lighting by arc lamps is making great headway in Paris, and that in consequence gaslighting is being discontinued in certain of the more important streets. Amongst these is the Rue de Rivoli, from the Louvre to the Hotel de Ville. We presume that when the municipal authorities acquire the electric lighting undertakings, as will be the case in the course of two or three years, there will be a large increase in the arc lighting of the streets of the French capital. At present the prices charged in Paris for electric lighting are excessive.

Manchester-Liverpool Electrical Express.—We understand that the new Bill of the Manchester and Liverpool Electric Express will be very different from that promoted last session. Instead of the line in the Salford district being on the viaduct principle, the whole of the three miles will be laid in a cutting. This will be covered over at intervals in a similar way to that in which the London underground was constructed, but instead of buildings being erected over the tunnels it is proposed to leave open spaces there, so that the Corporation may make gardens, and thus create a beautiful promenade a mile long through the worst slum property of the town. The capital of the company is now fixed at £2,100,000.

The Rontgen Society.—We are notified that an ordinary general meeting of the society will be held on Jan. 3, at 20, Hanover-square, W., at which Mr. A. W. Isenthal will read a paper on "Continental Progress in Practical Radiography and Apparatus." Before the paper, Dr. J. H Sequiera has kindly consented to show some cases of rodent ulcer treated with X-rays. The chair will be taken by the president (Mr. J. MacIntyre) at eight o'clock. Future arrangements include a paper upon "X-Ray Work during the Late Military Operations," by Lieutenant F. B. Bruce, R.A.M.C.; a discussion evening, the subject being "X-Ray Therapeutics," to be opened by Miss M. Sharpe, L.R.C.P.; and a paper by Mr. J. Cadett on "Some X-Ray Improvements." As in the last session, there will be an exhibition evening, and members are invited to bring skiagrams or other objects of interest.

Electric Light in Theatres.—A demand was recently made by the Licensing Committee of the Hull Corporation to force the manager of the Grand Theatre in Hull to use electric light for his projector work instead of limelight. We believe that, in accordance with the custom of the profession, we should say that the Licensing Committee tried to force the manager to use the "electric limes." The report of the city architect showed that limelight had been abolished in all the principal theatres of London, Manchester, Birmingham, and Sheffield, and that where it was still used in London the County Council required the limelight apparatus to be placed in special fireproof chambers apart from the main building. After hearing considerable evidence on the question, the committee did not feel justified in enforcing the architect's views, which is to be regretted, unless they enforced precautions to make the limelight safe.

The Bolton Tramways.—It is extremely important that the permanent way over which heavy tramcars such as are now used on electric lines should be accurately and truly laid. Any variation in the gauge causes undue wear on the wheels and also on the rails themselves. It also causes a considerable increase in the power required to move the cars. A case in point recently occurred in Bolton. It seems that when the Board of Trade inspection took place, the inspector advocated that the whole of the old tramway lines should be relaid. While it was hoped to save the big cost of this, it is now found by the borough surveyor that the gauge varies very considerably in different parts of the system. It is obviously impossible to alter the wheel tread to meet the defects, as there is a considerable difference between the gauge in the new work and certain parts of the old. The only thing, therefore, to be done is to meet the heavy expense of renewing the latter portions of the work before the wheels on the new cars are damaged by wear in passing over the lines.

Telephones in Glasgow.—The necessary underground conduits for the telephone system of Glasgow have already been mostly laid, and the work of drawing in conductors is being proceeded with. It is expected that the system will be complete and ready for working by the time the exhibition is opened next year. In view of the opposition which will thus be brought to bear on the National Telephone Company's exchange in Glasgow, the company are instituting improvements and concessions in order to hold their own if possible. Amongst the new introductions is the party line system, by which a large number of subscribers will use one line to the exchange. In Glasgow, where the houses are built to accommodate families in flats, this system can be comparatively easily employed, and the reduction in cost to the subscriber will make up to a certain degree the decreased convenience, for at busy times he may find his line to the exchange engaged. The minimum charge for such connections has been fixed by the company at 2d. per day, but payment will be made on the penny-in-the-slot system on the number of calls.

"The Journal of the Franklin Institute."—We have just received the December number of the above journal, which contains several items of interest to our readers. The first of these is a paper read in the chemical section by Prof. J. W. Richards on "The Use of Blast-Furnace Gases in Gas-Engines." As the figures given in the paper are almost all obtained from English and Continental sources, we do not propose to give an abstract of them at the present time, as all the data will shortly be given in our columns from a paper read before the Institution of Mechanical Engineers last week. Mr. W. A. Goodspeed's paper on "X-Rays and other Rays," read before the electrical section at the beginning of the year, has been referred to by us in previous issues, but it is reprinted in full in the journal before us. Another item which electrical engineers will do well to read is the report of the committee of the Franklin Institute on the Welsbach light. This report is a straightforward statement of the wonderful invention of Dr. Carl Auer von Welsbach. In consequence of this report, the Elliott Creeson medal of the Franklin Institute was awarded to this scientist.

Telegraphic Communication with the Continent We trust that the deputation recently sent to the Postmaster-General by the Liverpool Chamber of Commerce will have the effect of expediting the transmission of Continental telegrams to this country. At the present time the delays which occur in the telegraphic communications from the Continent are most serious, and in the memorial presented to Lord Londonderry the deputation name various reforms which the Chamber of Commerce consider necessary in order to render efficient the telegraph service between Liverpool and the other towns and the Continent. One of the proposals is that the French Government be urged to establish direct wires between Havre and the cotton manufacturing towns of the North and East of France. It is also suggested that new cables

Digitized by Google

to Germany, Belgium, and the Netherlands be provided. As to the means for effecting the improvement desired, it is pointed out that the Treasury, in order to provide properly for the commercial necessities of the kingdom and of a port of the rank of Liverpool, might apply some of the large profits of the Post Office and some of the increased Customs revenue derived from Liverpool to telegraph purposes.

Halifax Tramways.—It is gravely announced in one of the Halifax newspapers that the electric tramways are now being run at a loss. On looking through the paragraph underneath this heading we find that the period for which the loss is said to have been sustained is only one fortnight, and that this is due to a reduction in the number of passengers carried, which is usually found in Halifax in the winter months. Another point in connection with the loss which is worthy of note is that it is after paying interest and depreciation. In our opinion, the object of any municipal authority should be to so adjust its expenses and charges that there should be an extremely slight margin of profit after providing for the capital charges out of revenue. It seems that in the case of the Halifax tramways a profit was earned in the summer months, and that it has now, in the winter time, fallen down to a slight adverse balance. In the paragraph in question some interesting information is given as to the electricity required on the various roads. This is as follows: Highroad Well, 2·13 units per mile; King Cross, 1·54; Illingworth and Athol Mount, 1·61; Booth Town and Stump Cross, 2·08; Pellon, 1·84; and Savile Park, Salterhebble, and Skircoat Green, 1·61. The average income per car mile during the fortnight was 11d., and the cost, including interest on the sinking fund, 12·02d. per car mile.

Royal Meteorological Society.—The monthly meeting of this society was held on Wednesday evening, the 19th inst., at the Institution of Civil Engineers, Westminster, Dr. C. Theodore Williams (president) in the chair. Mr. H. Mellish read a paper on "The Seasonal Rainfall of the British Isles," which he illustrated with a number of lantern slides. He discussed the rainfall returns from 210 stations for the 25 years 1866-90, and calculated the percentage of the mean annual rainfall for each season. In winter the largest percentages of rainfall are found, as a rule, at the wet stations, and the smallest at the dry ones. Spring is everywhere the driest quarter, and the percentages are very uniform over the country—rather larger in the east than in the west. In summer the highest percentages are found in the dry districts, and the lowest in the wet ones. As the spring is everywhere dry, so is the autumn everywhere wet, and there is little difference in the proportion of the annual total which falls in the different districts. As regards the relation between the amount of rain which falls in the wettest and driest month at any station, it seems to be generally the case that the range is larger for wet stations than for dry ones. In wet districts rather more than twice as much rain falls on the average in the wettest month as in the driest, and in dry districts rather less than twice.

Electric Tramway Traction. — Last week Mr. A. W. Greatorex read a paper on "Electric Tramway Traction," the occasion being a meeting of the members of the Association of Birmingham Students of the Institution of Civil Engineers. The author first described the advantages and disadvantages of the overhead trolley wire, the conduit, the accumulator, the combined overhead and accumulator, the combined overhead and conduit, and the surface-contact systems, and illustrated his remarks with lantern slides. He expressed the opinion that the overhead trolley wire system was at present the best adapted for tramway work in the majority of towns in this country. In London, however, where tramway extension was inevitable, and where the traffic would pay for almost any capital invested, the overhead wires would probably not be admitted within a radius of three or four miles of Charing Cross, but beyond that limit trolley wires must be used. He advised municipalities to take up the tramway question, and not allow outside companies to carry on the enterprise. In his opinion the profits reaped from the tramways should be applied to a reduction of the rates. He was further of opinion that general power should be granted to local authorities to form joint boards, that corporations should have running powers over outside lines, and in the case of large towns like Birmingham the corporations should take over the control of the tramways within a certain area, and pay a rental to the smaller places. We do not agree at all with the author that the municipal authorities should make a profit out of the tramway passengers to be applied to the reduction of rates.

The Manhattan Railway.—In the derogatory remarks which were made by certain American engineers with respect to the Metropolitan District Railway Company, it is interesting to note that an experimental electrical train has recently been tried on the Manhattan Railway at New York. These gentlemen scoffed at the very idea that any experimental train was required order to prove the practicability of electric traction on the underground. In spite of this, the Manhattan Railway authorities have found it advisable to follow the example of the Metropolitan District Railway. In the train which was tried on Nov. 22 a still further similarity exists between it and the English practice. There were six cars employed, the end two being motorcars, which is the case on the Waterloo and City Railway. Eight motors were used on each train, four on each motorcar, and they were all controlled simultaneously from either end of the train. This entailed a cable running the full length of the train, as is also the case on the Waterloo and City Railway. The line voltage employed was 550 volts, and the train took a maximum current of 1,500 amperes when accelerating. The full figures of the trial are not yet available. One noteworthy fact, however, is the statement that the present average speed on the rails with steam is from 11 to 12 miles per hour, while 14 miles is expected when the electrical equipment is employed. It will be remembered that the average speeds, including stops, actually obtained on the Central London Railway is 12 miles per hour, whereas on the Metropolitan District Railway with steam locomotives the speed during the evening rush is 11 miles per hour.

Engineering Progress Abroad.—A lecture was delivered recently before the Bradford Municipal Technical College by Mr. G. F. Charnock on his visit to the Paris Exhibition and to some Continental engineering works. The lecturer is the headmaster of the college department of civil, mechanical, and electrical engineering. In the lecture it was regretted that, while all foreign nations had learnt their trade in steam-engine building and like work from Great Britain, our country should not have been more largely represented at the Paris Exhibition. This was particularly so, as our foreign competitors exhibited most largely. He thought that English manufacturers now had much to learn from what was exhibited in Paris. After referring to the few exhibits there were of English-made engines and dynamos. the lecturer went on to comment on other plant he saw when travelling through Switzerland, and the good work done by the firm of Brown

Digitized by Google

and Boveri. This led on to the question of three-phase working, in which this country was behind. He regretted that we had not done more in this direction, in spite of the fact that we had not the large water power which had made the system such a success in Switzerland. We were unable in consequence to compete with foreign firms for work in our Colonies. It was worthy of note, the lecturer thought, that Switzerland had succeeded so well as a manufacturing nation notwithstanding the high price of coal in that country. He also stated that wages were high, but in this we cannot agree. The lecturer's conclusion was that in this country draughtsmen and designers were not considered as they should be, and were not paid sufficiently well. He hoped that the advance of technical education would do much to remove the faults to which he had alluded.

The Light Cure.—We notice that the *Deutschen Medizinischen Wochenschrift* has published a communication by Dr. H. Strebel, of Munich, on the deadly effects produced by the invisible rays of the electric discharge upon bacteria. The doctor, it seems, has succeeded in proving that the invisible rays of a powerful induction spark are capable of killing strong cultures—for instance, of micrococcus prodigiosus—within the short space of, say, 20 minutes, even through a thick medium of quartz. The induction spark is naturally rich in ultra-violet rays, but by employing certain substances as electrodes and a Leyden jar as a regulator and accumulator of the electricity, the richness of the spark in ultra-violet light may be enormously increased. Dr. Strebel used electrodes of aluminium and cadmium, when the ultra-violet portion of the invisible spectrum, rendered visible to the eye by projection on to a fluorescent screen, exceeded the visible portion of the spectrum by more than four times in length. Further experiments showed that the invisible ultra-violet rays, after the passage of light rays through a system of Finsen filters, had been completely absorbed by the apparatus, and that the destructive chemical influence which the apparatus had upon bacteria was due entirely to the agency of the visible rays, especially those of the blue-violet order. But the latter rays have but little chemical effect compared with the invisible ultra-violet rays, wherefore the success of the experiment bears very largely on the improvement of the light-cure process—that is to say, the strengthening of the bacteria-killing capacity of the light—besides the simplification and cheapening of the process, for compared with the 80 amperes required by the Finsen filtering apparatus, only a very small current is involved in the case of the Röntgen apparatus. Dr. Strebel has also been engaged in investigating the permeabilities of different mediums for ultra-violet rays and their influence on different kinds of bacteria.

Electric Railway Dispute.—An action between the Great Northern Railway Company and the Great Northern and City Railway Company, recently heard in the Chancery Division of the High Court, has resulted in an important gain for the former. It would appear that the City Railway Company obtained parliamentary powers in 1892 for constructing a line to be worked by electricity in the neighbourhood of Finsbury Park Station on the Great Northern Railway. The Act provided that the City Company should use Finsbury Park Station for local traffic, and there was to be a connection near Finsbury Park Station for an interchange of through traffic. To carry out the latter scheme Sir Henry Oakley estimated that about £1,000,000 sterling would be required. Negotiations resulted in an agreement of January, 1894, and it was as to the true meaning of this document that the question turned. The plaintiffs' case was that under the agreement two substituted lines were to be made at an estimated cost of £167,000, and that they were to pay the City Company £20,000 for the transit of their traffic over the defendants' lines. The City Company, however, argued that the works to be carried out under the agreement were additional to those authorised by the Act of Parliament, but this interpretation did not find favour with Mr. Justice Buckley, who tried the case. The learned judge refused to accept the contention that it was intended to have a duplicate system of construction between the places named, and his decision, therefore, was that the connecting lines were in substitution for those in respect of which parliamentary powers were obtained in 1892. By the judgment of Mr. Justice Buckley the City Railway Company are now restrained from proceeding under certain notices to treat in respect of the first proposed line, and the Great Northern Company have secured the costs of the litigation.

Insurance Rates.—Within the past few years there has been frequent trouble between fire insurance companies and electrical engineers over the question of insurance rates. Perhaps the most attention has been attracted to the insurance rates for electricity works, which in most English offices are unduly high. The reason for this is that certain electricity works which were first established in London were put together in the early days of electric lighting, when the use of fireproof materials had not become so common as at present. In a few of these cases there have been serious fires, and the insurance companies have had to bear the brunt in consequence. It is most unfair, however, that all new electric stations in which every precaution is taken against fire, should be penalised by heavy insurance rates because the companies lost on their earlier policies. As the bulk of the English companies work on a common tariff, the only way of reducing these high premiums is to induce one of the non-tariff offices to look at the matter in the proper light. This course has been pursued with considerable advantage to all concerned. Another phase of the question of insurance rates for electrically-lighted houses has still to be solved. Thus, while it has been proved by the returns of the fire brigade department of the London County Council that electric lighting is the most safe illuminant, there has been up to the present no acknowledgement of the fact in the premiums demanded by fire insurance companies. We are now able to state that the Fine-Art and General Insurance Company, Limited, are prepared to grant reductions off the current rates for insuring private houses and business premises in which electric light is the sole illuminant. The *sine qua non*, however, is that the work should be carried out by fully qualified and experienced engineers, and we presume that the company will inspect the electric lighting arrangements before giving any reduction in the premium. If this is done, there are sound reasons for giving the reduction, and we trust that the financial results will induce other offices to compete with the above company on the reduction of rates. It is hinted in the notice before us that the reduction will probably be not less than 10 per cent. in the present premiums.

Electric Traction on Railways.—In addressing a meeting of the Cologne Association of Electrical Engineers recently, Herr Bork, director of railways, made some interesting remarks relative to the prospects of the introduction of electric traction on to the standard-gauge railways in Germany. He pointed out that railways had been projected for speeds of from 100 to 150 miles per hour, but their realisation was not in prospect, because even the estimated saving of half the time taken by a railway

Digitized by Google

train of the ordinary type to accomplish a given distance did not justify the enormous outlay which such schemes would entail. Schemes had also been devised whereby it was sought to obtain very rapid acceleration upon starting, which doubtless the question of cost had likewise upset. The directors of the State railways recognised the great advantages offered by electric traction for railway work, but could decide upon its introduction only after the working costs pertaining to the same should have proved themselves to be at least no higher than those holding for the existing system. The arguments in favour of the adoption of electric traction for very busy stretches of railway in thickly populated districts were very strong, and for this reason the directors of the Prussian State Railways had inaugurated a practical test over a section of line where such conditions prevailed—namely, the Wannsee railway between Berlin and Zehlendorf. Much had already been written about the equipment of this line. No interruptions of the service had yet occurred, though the winter with its attendant snow and ice had still to be experienced. The available figures showed a saving of over 10 per cent. in the working costs of the system as compared with the steam locomotive service, added to which the trial train ran much smoother and attained its maximum speed in the space of two minutes as against the three minutes occupied by the steam locomotive. With stations situated at four-minute intervals, this represented a shortening of the time of travel without an attendant increase of the maximum speed. The current consumed varied up to 1,200 amperes, while the energy required amounted to 32 watt-hours per ton mile. With regard to the actual cost of working, this would probably amount to 8d. per train mile, as compared with 8 12d. for the steam locomotive service.

Self-Propelled Traffic.—At a meeting of the Liverpool Self-Propelled Traffic Association recently, the report of the fourth session was presented. It stated that the judges' report on the 1899 trials of motor vehicles for heavy traffic, which had been ordered from all parts of the civilised globe, was now out of print. It was resolved to give particular attention to the matter of an increase of tare, the arguments in favour of which were chiefly: (*a*) to secure equal treatment with horse-drawn traffic; (*b*) to ensure the safety of the public; (*c*) to meet commercial requirements; (*d*) to meet foreign competition. In their report the judges of the Liverpool trials drew attention to the risks involved in attempting to work under the tare limit of the 1896 Act. They concluded that even for loads of four tons carried on the maximum tare allowed, "the strength of frames and working parts, the areas of bearing surfaces, the width of wheel types, the available platform area, the stoutness of the platform and woodwork generally, and the diameters of axles and shafts were reduced below what is compatible with a satisfactory life or the safety of the public" Whatever the risks, they are due to the fact that the present tare limit precludes the use of adequate material and strength in construction. The alternatives presented to the manufacturer at present were either to charge a prohibitive price or to reduce factors of safety to a dangerous extent. If the tare weight were increased, proper design would be possible without any concomitant disadvantage, and the means of control could be perfected in all directions. It was a hardship that Great Britain should be hindered by legislation where the Continent (particularly France and Germany) and the United States had freedom for development. If the tare limit was not increased immediately, foreigners would obtain so great a lead that Englishmen would have enormous difficulty in competing with them later. France, Germany, and America, the last-named most of all, were building motor wagons even now in much larger numbers than were being built in England, and were aiming at loads above four tons upon vehicles with tares above three tons. In regard to the 1901 trials, it was reported that a conference of manufacturers was held in Liverpool in May last, when the conditions for the third trials of motor vehicles for heavy traffic were discussed. The particulars and regulations were issued on June 13, the dates for the trials being June 3 to 7, 1901. The routes which have been selected embrace Widnes, Warrington, Manchester, Bolton, Wigan, St. Helens, Chorley, Blackburn, and Preston. The committee of the Automobile Club, we hear, have accepted the invitation of the association to arrange a tour down to Liverpool during the trials.

Street Subways.—We have again and again advocated that the great obstruction of traffic, and the expense entailed in consequence of the delay in traffic, due to the opening up of the London streets, should be avoided by the construction of subways in which all distributing systems for electricity, water, gas, and hydraulic power might be laid. It is an exceedingly difficult thing to get at the true loss caused by these obstructions, owing to the fact that the losses are indirect and involve a reduced efficiency of transport rather than a direct increase of cost. The large omnibus companies know how many journeys per day they lose owing to the streets being up, and in this loss, it must be remembered, there is no account taken of the time the omnibus drivers and conductors lose. There is one way, however, in which some idea of the value of the subways can be obtained, and it has been investigated by a writer in the *Daily Mail*. He claims to have looked into the actual outlay of the various companies in London during the past five years for excavating and making good the public streets, and the extreme accuracy of his figures makes one believe that he has actually had access to the books of the companies. For instance, he states that three large gas companies have expended no less than £3,747,152. 12s. 2d. in road work during that period. The electric light companies and local authorities are said to have spent £2,554,900, while the water companies' expenditure amounts to £2,892,188, out of which only a small proportion was due to damage caused to their pipes through frost. The telephone company is said to have spent in street work £1,369,498. 12s. 3d., so that the grand total is over 10½ millions. The contributor goes on to state that large tunnels could be constructed in the principal streets of London at an average cost of £25 per foot. If this figure be accepted as accurate, the total expenditure for equipping 75 miles of the London streets would be some 15 millions, and it will be seen that the companies would save this value in a comparatively short period. The question, however, is as to who is to bear the cost of laying down the complete new system of conduits in the subways if constructed. It must be remembered that, in addition to the 10½ millions referred to above, there is also the cost of the materials laid in the trench when excavated. Almost all this would be wasted if the present pipes and conduits had to be moved into a big tunnel down each street. It is this interference with the vested interest of private companies that makes it so difficult to act, but we trust that the construction of subways will be commenced before long. It is a great pity that they were not commenced a few years ago, for in that case the excessive obstructions at the present time, due to the simultaneous laying of telephone conductors and electric lighting mains in the City of London, might have been saved.

PRACTICAL NOTES ON ELECTRIC MAINS.

BY A MAINS ENGINEER.

(Continued from page 873.)

Bare copper systems take up much more room than any one of the foregoing, as a large concrete culvert has to be built before the copper strip is put into place. The greatest claim, perhaps, that can be made for copper strip is that it never alters its insulation value however much jointing is done on it, whereas the insulation value of a cable is lowered immediately a joint is made on it. Another thing claimed for it is the facility it offers for the connection of services. This, however, is not worth so much as it appears to be at first sight unless two or more services come within short distances of one another. It is nearly always the case that the going to a job and the general running about takes more time than the making of a service joint.

Bare copper strip has also one very great disadvantage at the time of a fault occurring. If the strip lies directly in the path of the current taken by a fault, the strips set up a swaying motion, and are often drawn together, thus making a fault which it is of no use whatever to try to burn out. This might be overcome by placing the bearing bars closer together than customary, and also seeing that the insulators and carrying caps fit better than usual, thus making a more rigid holder for each strip. Also it would be as well to place a riding insulator midway between each two bearing bars, thus making it absolutely impossible for the strips to come together. It is usual to place a cast-iron frame and lid over each bearing bar, thus making an inspection box. Into these boxes the service wires are brought. The lids and frames are not so large as they might be, as if the strip is very deep, a man cannot get at the strip to make the necessary connections. This, of course, could be altered easily. The lids should be carefully filled, and not filled too high, otherwise they form little lumps above the surrounding pavement, and so are unsightly and dangerous. When building a culvert for bare copper mains it is necessary to take levels, so that each length of culvert is drained into a manhole, which manhole is in turn drained into the nearest sewer through a non-return trap. The culverts, because they are so large, must also be ventilated. This can be accomplished at the manhole covers. Manholes are usually placed at street corners—*i.e.*, one on each side of a cross street, the cross street being crossed by cables laid on the solid system. Gas and water service pipes should never be allowed inside a culvert, and the building of a culvert is often expensive owing to such services having to be shifted, or if this cannot be done, by having to dig deep enough to allow of the culvert passing underneath the services.

After the strips have been drawn through the culvert they are tightened up by means of ratchet gear, and when tight enough are fastened by means of set screws bearing directly on the strip, these screws being placed in each manhole. If the strip is laid during winter time, it ought to be stretched tighter than if laid in summer time, as if it is not drawn tight enough in cold weather it will sag very much in the warmer weather. There is very little doubt that if bare copper could be laid everywhere throughout a town or district, and no other system used in conjunction with it, and any services taken off it were laid solid, absolute freedom from bad faults would be obtained.

Before commencing to open ground for any system, the town surveyor's maps should be consulted to ascertain the position of gas and water mains, sewers, etc.; notices should be sent to the various municipal departments to the effect that openings were intended to be made. Trial holes should be opened two or three days before a gang of men is sent on to the job, and the job should be carefully considered as to the number and size of cables required. The size of cable required can be worked out according to the value of the house property which it is intended to serve *en route*, the $C^2 R$ of the cable also being taken into account Of course, houses and shops are not always of the same value in different towns, but it will be found that the average £40 house requires about 1,000 watts and the average £60 shop requires about 2,000 watts: this is if the shop is what is known as a lock-up shop; if the house part is inhabited, of course more must be allowed It is a good plan to lay a line of, say, 4in. glazed earthenware pipes along the cable route to provide for any emergency that may arise; an extra cable could then at any time be drawn in without again disturbing the ground. Cables for street-lighting purposes are also best if they are separate cables from the distributors, and better still if they are separately controlled right from the works.

Having chosen a clear route, a gang can be sent on to the job well provided with tools, timber, rope, and other requisites according to the system to be laid. The best picks are those with iron-shod shafts, as the wood shaft wears away through the friction of the steel pick eye. The gang should consist of about 25 men to one foreman. If the number of men is doubled, then a sub-foreman should also be sent. Twenty-five men are quite enough for one man to look after properly. With a large gang, working in a large district, where many of the men come several miles to their work, it is usual to tell off one man to warm the food for the rest, to boil water for them, etc. This man during spare time can clean and trim the watch lamps for the night. The watchman should arrive at his work just before the gang knock off, and the cable-laying foreman should never leave the job until he has seen the watchman at his post. The watchman should be well provided with good lamps, guard ropes, and iron pins, as in a busy town it is necessary to rope off everything, even to the smallest heap of soil. In case an accident happens while the watchman is on duty, he should be instructed to forward to the engineer a detailed report of what has occurred at the earliest possible moment, giving the names of any witnesses, which he should always endeavour to get. The best witnesses are policemen. Where several gangs are employed in one town it is a good plan to have a foreman watchman, who goes from one job to another during the night. One watchman can easily watch about 200 yards, his cabin being placed in the centre of the length. It should always be borne in mind that people have a great knack of having accidents on municipal jobs, as the municipalities so easily pay damages: therefore everything that can be done to avoid these should be done.

When opening the trench, if it is found that gas and water lead service pipes show all along the bottom of the trench, then it is best to open again below these services, as many services are damaged by drawing in on top of them; armoured cables especially soon rub holes through. Any damage to such service pipes should be immediately reported to the department to which the pipes belong, and pending the arrival of the men to repair, the damaged service should be hammered up between the damage and the main from which it is supplied. If a gas or water main is bared for any considerable length, it should be slung with chains suspended from stiff timbers laid across the trench. The chains should be placed immediately behind the socket of the main so bared, and can be tightened by what is known as a Spanish windlass, really forming a tourniquet. The bared main might also be propped with bricks from the bottom of the trench, but these bricks are apt to be in the way.

When opening along the side of a wall, if it is found that the wall has no foundation, as is often the case with garden walls, the wall must be propped by oblique struts, the feet of the struts being let into the ground outside the trench—*i.e.*, on the side of the trench farthest away from the wall. The ends which go against the wall are cut so as to present a face parallel with the wall, vertically and horizontally; a board is then inserted between these cut faces and the wall, the end of the struts being nailed to the board. If the brick arch of a large culvert or underground brook has to be cut away, a casting should be made as shown in Fig. 4. The insertion of this casting prevents the sides of the culvert from collapsing inwards. Wrought iron would be useless, as it very soon rusts away.

As soon as a trench is opened, carts can be employed to take away some of the soil, the amount to go away being governed by the bulk of new material to go in. If only one armoured cable is to be laid direct in the ground, there will probably be no need to send any soil away. A place to tip carts must therefore be arranged for. Material should as far as possible be delivered on the job by the makers of the material, or by the railway companies who carry it. Thus much cartage expense is saved, for railway companies are bound to deliver within a fixed radius.

When drawing in cables always have as long a draw as

Digitized by Google

possible; do not flake the cable more often than can be helped. As much as possible place all the strength at the end of the cable: the cable is then kept more in a straight line than if the men were at equal distances along the cable with small concentric cables, whose conductors are formed of small wires, there is danger of the outer wires breaking and the broken ends piercing the inner dielectric if the cable is not kept straight. It is almost impossible to hurt an armoured cable by drawing it along the ground, providing it does not catch anywhere. Always draw the cable from underneath the drum; fewer accidents will happen if so drawn. See that the cable in running off the drum does not rub on the side of the drum, especially if the cable be unarmoured. Do not pull the cable too tight, especially if laid in very hot weather, as it will shrink during the next cold weather, probably causing straight joints to pull in two, thus causing a discontinuity fault. Two hundred yards are quite long enough for the smallest cables; large cables can well be shorter.

When a road has to be crossed, it often has to be opened in twice. Care should then be taken to see that no large gas or water mains come close to the end of the first opening; if so, sufficient room for bending in the remaining length of cable may not be obtained. The radius of any cable bend should not be less than ten times the diameter of the cable. If cable ends have to be buried in the ground to await jointing, the cable-laying foreman should have the ends placed in wooden boxes about 14in. long. These boxes should then be filled with bitumen. This should always be done whatever

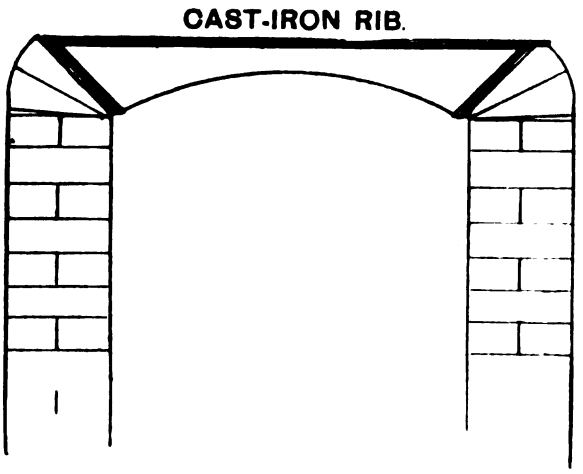

FIG. 4.—Arch Casting.

class of cable is used. The foolish plan of letting rubber insulated cable ends get wet should not be allowed. If a cable is cut, the end should immediately be dipped into hot box compound, which will effectually keep it dry, as it adheres to the cable much better than bitumen does. Cables should be lapped over not less than 2ft. 6in to allow for testing and jointing. Positions of all joints and ends should be carefully noted by the laying foreman. It is well, if it can be managed, to let a jointer follow up the gang, testing and jointing before the ground is filled in. Careful records of all cables laid as to position, as well as position of joints, should be kept, the cables being marked on the Ordnance Survey maps. This job can be undertaken by the mains engineer if the district is a small one, but is better done by a draughtsman if much work is going on. It is, however, absolutely necessary that no mistakes should be made.

Although a thin wall of insulation may stand double the working pressure of a cable, still, for mechanical reasons, no cable should be laid that has an insulation wall less than $\frac{3}{16}$in. in thickness. Rubber-insulated cables should be insulated by cross lappings of rubber in strip, and not by the two sheets of rubber, one above and one below the copper core, whose edges meet, and so unite. Very often, if they do unite, as we are told they do, they come apart again, thus giving trouble. A system which some engineers may at some time like to try is at present in the writer's mind. The suggestion is offered for what it is worth; probably the Board of Trade might not allow it. On a three-wire network a cable might be composed (in the form of a triple-concentric) of an inner copper core, an intermediate copper conductor, and the outer conductor, which would be used as the neutral wire, would be made of iron, and would serve two purposes, one as a conductor and one as a protector, really an armour. Such a cable might then be laid solid, preferably in an earthenware trough. As on a *perfectly* balanced three-wire network no current flows along the middle conductor, the greater specific resistance of the iron would not matter. The best form for the iron would be that of small iron wires braided closely.

(To be continued.)

INCREASING THE EFFICIENCY OF STEAM-ENGINES.*

The recent centennial anniversary of the Royal Technical High School at Charlottenburg was made the occasion of several important announcements concerning the work of that renowned institution, which embodies in a remarkable degree the advanced technical science which has done so much to push Germany forward into the front rank of manufacturing nations. Among these, the first rank is by common consent accorded to the paper of Prof. E. Josse, head of the mechanical laboratory, in which are described with elaborate detail the results of his experiments with an original and highly interesting process for increasing the efficiency of steam-engines by utilising the heat of the exhaust steam for evaporating another liquid having a lower boiling point than water.

It is well known that the steam boiler and engine, notwithstanding all improvements which it has undergone during the past 100 years and its incalculable services to mankind, is, nevertheless, a wasteful and extravagant device for converting the energy stored in fuel into mechanical power. The ordinary simple high-pressure engine, which after passing steam through one cylinder discharges it into the air, utilises hardly more than 5 per cent. of the value of the fuel consumed under its boiler. The compound engine, in which the steam, after passing successively through two, three, or more cylinders, is condensed, and the warm water of condensation restored to the boiler, utilises under favourable conditions 12 to 13 per cent. of the fuel energy, and there the economy appears to have stopped. An eminent American engineer has recently published an article reviewing the development of the steam engine, and closes his essay with the expressed opinion that with the compound machines and improved cut-off of recent years the practical limit of efficiency of the steam-engine has been reached. The invention described by Prof. Josse introduces a novel element into the problem, and opens a new chapter in the record of steam-engine development.

The process is the joint discovery of Mr. G. Behrend, a Hamburg engineer, and Dr. Zimmermann, of Ludwigshafen; and, although first patented in 1889, it has only recently been matured and its application perfected by the employment of an auxiliary engine, which, utilising the heat contained in the exhaust steam, gains as high as 56 per cent. additional motive power without increasing the expenditure of fuel. The principle and process involved are simple, and may be briefly described as follows:

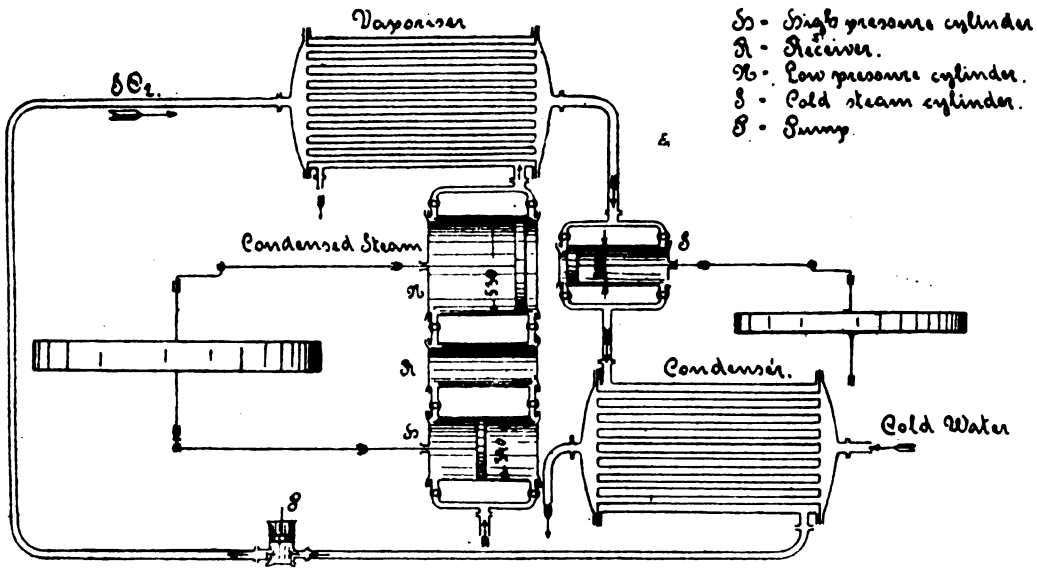
It is plain that with all progress which has hitherto been made in steam-engine practice through higher pressures, superheated steam, economical cut-offs, or successive cylinders, there is always an important and inevitable loss of heat energy when the steam, having done its work, is discharged into the open air or changed back to water by contact with cold water in a condenser. When the exhaust is into the open air, the steam has a temperature of about 100deg. Celsius (212deg. F.); when it passes into a condenser, the steam has a temperature of 60deg. to 70deg. Celsius (140deg to 160deg. F.), according to the vacuum. The corresponding latent heat of steam, given up upon change of form from steam to hot water, has hitherto run to waste in the condensing or cooling water, or in the air. Messrs. Behrend and Zimmermann attacked the problem of utilising this wasted caloric by employing it to create a new supply of steam by evaporat-

* Consular Report, U.S.A.

Digitized by Google

ing some liquid which has a lower boiling point than water, and for this purpose they chose, after many experiments, sulphurous acid (H_2SO_3), which is not only cheap and easily obtained, but has the further advantage of a viscous consistency and lubricates the inner working surfaces of the machinery without corroding them. Their demonstrations, although not practically conclusive, were so promising that Prof. Josse, as a technical authority on this subject, took up the problem, and, after several months of highly satisfactory laboratory experiment, caused to be constructed and connected with an ordinary working steam-engine of the compound type an additional condenser and auxiliary engine, the power of which could be exactly measured. The whole working apparatus is shown in the engraving herewith submitted, and the technical details will be explained by the drawing, and may be thus described.

Referring to the diagram, in which dimensions are given in millimetres, H and N represent the high and low pressure cylinders of an ordinary compound steam-engine, with a stroke of 500mm. (19·69in.) and a speed of 41·5 revolutions per minute. From the low-pressure cylinder, N, the exhaust steam passes into the surface condenser, called in the diagram the "vaporiser.' In this vaporiser, or condenser, the cooling medium used, instead of water, is liquid sulphurous acid (H_2SO_3), which has a boiling point so low that it is immediately decomposed by the heat of the exhaust steam, whereby the sulphur dioxide



gas (SO_2) is liberated, which passes over into the cylinder of the auxiliary engine, S, where its work is done as in an ordinary steam-engine. The auxiliary cylinder has a diameter of 300mm. (11·81in.) and a stroke of 500mm., with a speed of 77 revolutions per minute.

After passing through this cylinder, the sulphurous vapour enters the surface condenser, around the tubes of which cold water flows as in an ordinary steam plant. Here the sulphurous vapour is condensed to liquid and is forced by the pump, P, back into the vaporiser, where it begins its cycle again, the same SO_2 being used over and over again indefinitely. There are therefore, in fact, two condensers, the first serving, as it were, as a boiler or steam generator for the auxiliary engine; and this boiler, instead of being fired by coal, obtains all its heat from the exhaust of an ordinary steam-engine, and instead of converting water into steam, evaporates a liquid which is much more volatile—*i.e.*, has a far lower boiling point.

In the long series of recorded tests with the plant shown in the engraving herewith transmitted the following results were attained:

The steam-engine is of the compound type, of good, modern construction, and, being given a steady load, developed 34 i.h.p., with a consumption of 8·6 kg. (18·96lb.) of steam per indicated horse-power hour. The auxiliary machine working with the sulphurous vapour indicated 19 h.p.—that is, an increase of 56 per cent., and yielding, instead of 1 h.p., 1·56 h.p. for the same steam consumption and reducing the steam constmption from 8·6 kg. to 5·5 kg. (from 18·96lb. to 12·13lb.) per indicated horse-power.

The experiments showed on the average that for every 15 kg. (33·169lb.) of steam passing through the main engine, 1 h.p. could be gained in the auxiliary machine. Applied, therefore, to an ordinary single-cylinder steam-engine, exhausting into the air at high temperature, the percentage of power saved by this new device would be very much higher than the economy reached in these experiments, which, as has been shown, were made with a highly improved compound engine. From the average of these experiments, it may be broadly stated that, given a fairly economical compound engine, using 7½ kg. (16·5lb.) of steam per indicated horse-power hour, half an indicated horse-power could be produced in the auxiliary machine for every indicated horse-power developed in the main engine. Assuming an average vacuum of 60cm. (23·62in.), corresponding to a temperature of 60deg. Celsius (140deg. F.), the saving of heat must be accomplished by using a liquid which can be vaporised to a high pressure at or below that temperature. Assuming, further, the upper and lower limits of temperature within which the operation is confined to be 60deg. and 20deg. Celsius (140deg. and 67deg. F.), the pressure of the sulphurous vapour would range from 10·05 down to 2·35 atmospheres above open-air pressure. A working pressure as high as ordinary steam-boiler pressure is therefore readily obtained at a comparatively moderate temperature. Moreover, the volume of sulphurus-acid vapour necessary to contain the number of heat units corresponding to the work to be performed is much smaller than the volume of steam which would be required for the same purpose. As the saving to be effected by the auxiliary engine depends directly upon the difference between the highest and lowest temperatures involved, the greatest gain will, therefore, be made either when the water in the surface condenser is as cold as possible or when the heat of the exhaust steam from the engine is at a maximum, as is the case with a single-cylinder steam-engine without condenser, which may be anywhere up to 212deg. F.

The expense of this improvement is practically all in the construction cost of the vaporiser, condenser, and auxiliary engine itself, and its economy may be realised from the fact that the exhaust steam from a 2,000-h.p. central-station engine should furnish power to drive an additional 1,000-h.p. engine, which can be connected as an extra cylinder to the steam-engine or run independently, and thus increase by 50 per cent. the power developed without adding a pound to the quantity of fuel consumed. When in view of the present coal famine throughout Europe it is remembered that the steam-engine energy of Germany alone, afloat and ashore, is not less than 3,717,264 h.p., the commercial importance of such an improvement will be readily apparent.

POLYPHASE ELECTRIC TRACTION.*

BY PROF. C. A. CARUS-WILSON.

PART II.—ACCELERATION TESTS ON THE BURGDORF RAILWAY

(Concluded from page 851.)

Method of Deducing Results.—The apparent power input, obtained by multiplying together the instantaneous values of the voltmeter and ammeter readings, was plotted in kilowatts as a curve on a time base, and continued up to the point at which full speed was reached, as shown by the speed indicator readings, which were plotted on the same base. The power factor for any given watt input, being independent of the rotor resistance, is the same as when the motor is running synchronously with an equal input and with short-circuited rotor, and can be found from the curve given in Fig. 33. The true watt input was thus obtained and plotted beneath the curve of apparent watt input, the area enclosed by the curve giving the energy expenditure in watt-hours up to any given time. The weight of the train being known, the number of watt-hours per ton expended in bringing the train to full speed was then determined. In all the tests the experimental train started at the points shown in Fig. 4, and moved in the direction of Burgdorf, thus encountering successively a 300m. curve, a main-line crossing, and a second 300m. curve. After starting, the train ran for a distance of 1,700ft. on a level before reaching the grade of 1 in 47.

Criticism of the Tests.—Three sets of experiments were made with different trains—namely, one set of four tests with one motorcar and three trailers, the total weight being 68 tons; one set of three tests with one motorcar and two trailers, the total weight being 56 tons; one set of two tests with the motorcar by itself, the total weight being 32 tons. The observations obtained in two tests out of each set have been plotted and are given in Fig. 20. The automatic speed records are given in Figs. 21 and 22. At the time the tests were being conducted the automatic regulators governing the motion of the turbines in the power-house at Spiez were being overhauled, and consequently out of action, the governing being performed by hand. The result was that the speed of the generator, and hence the frequency, varied considerably, and this was shown in a variation of the speed of the train when full speed had been reached. The variations in the power input are due in part to irregularities in handling the controller, but the most important variation is caused by the large drop that takes place in the tension. The transformer stations are about two miles apart, and the tests were conducted on a portion of the line about midway between two stations, and, therefore, at a point where the drop is a maximum. The effect of the drop is shown in the diminished input and the consequent reduction of torque and acceleration at the moment of starting, resulting in an energy expenditure about 10 per cent. more than would be required if the tension were kept constant. The speeds given in Fig. 20 were obtained from the indicator readings in all cases but that of Test No. 3, where they were deduced from observations made from dropping clay balls on the track at noted time intervals and afterwards measuring up the corresponding space intervals. In Test No. 1 the motors were switched off before full speed had been reached. In Test No. 7 the trolley jumped off the overhead wire when the car struck the main crossing, causing a drop in the power input and in the acceleration.

Chicago Railway (continuous current)	—	23	9·5	1 12	30	75	34·7	330
" " "	—	24	9·5	0 95	37	75	39 5	375

The Results of the Tests.—The areas of the true power curves in Tests 3, 6, 8, and 9 have been calculated up to the point at which a speed of 23 miles per hour, or 33·6ft. per second, was reached, and the areas of the curves in Tests 8 and 9 have also been calculated up to 24 miles per hour, or 35·2ft. per second. The results are given in Table II. The energy expended per ton of load moved increases with the number of tons per motor. The reason of this is that the energy is proportional to the time occupied, and the time increases in a greater ratio than the load. Thus, if the load per motor is increased by 75 per cent., the time is increased 100 per cent. and energy per ton 14 per cent. This shows the importance of ample driving force, and the value of high initial acceleration in obtaining good efficiency. The best results were obtained in the tests with the motorcar alone, when each of the four motors had to move a weight of only eight tons, and of these results the lowest energy expenditure was observed in Test No. 8, where 41·5 watt-hours per ton was the energy expended in getting up a speed of 23 miles per hour. With the motorcar and two trailers, giving a weight of 14 tons per motor, the energy expenditure rose to 52·8 watt-hours per ton. In calculating these results, the power factor has been taken rather too large, so that the actual energy expenditure is somewhat lower than the values given above.

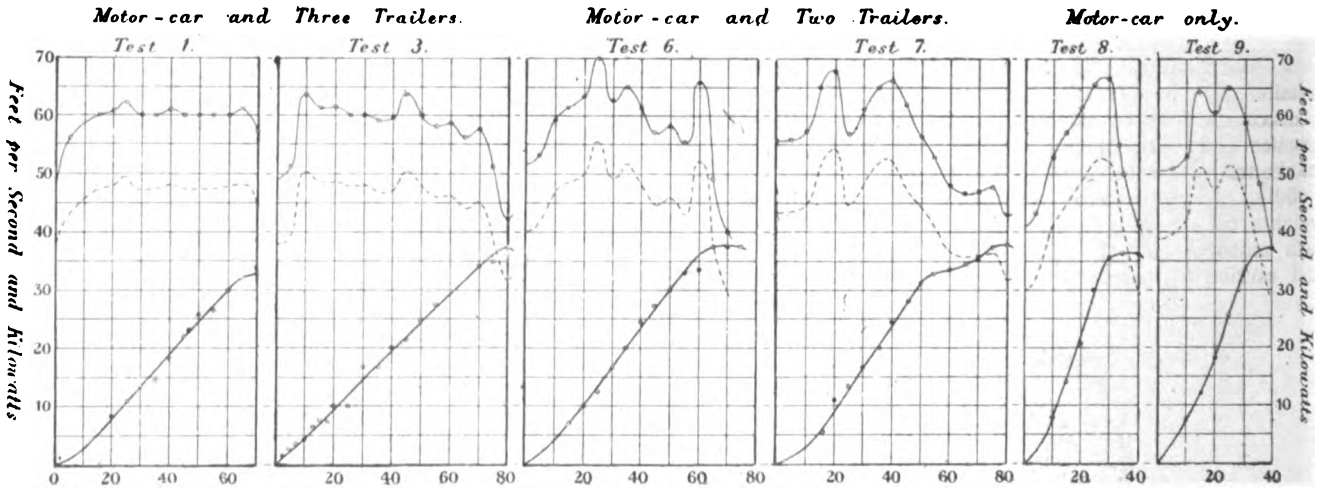

FIG. 20.—Acceleration Tests, Burgdorf-Thun Railway.

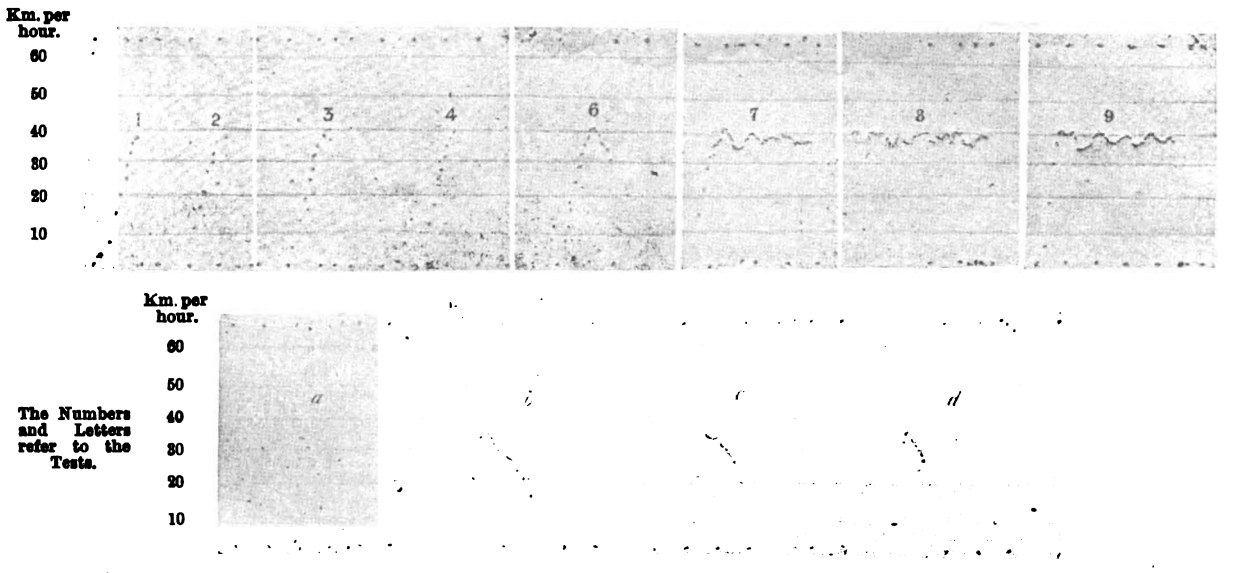
* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

Comparison of these Results with those obtained with Continuous Currents.—One of the most recent continuous-current railway equipments is that installed on the South Side Elevated Railway at Chicago, a full account of which was given in a paper read by Mr. F. J. Sprague before the American Institute of Electrical Engineers on May 16, 1899. The trains on this railway are made up of motorcars operated on the Sprague multiple-unit system. Each car weighs 19 tons, and is equipped with two motors



FIGS. 21 AND 22.—Full-Size Automatic Records of Acceleration Tests.

making 9·5 tons per motor. The diameter of the driving wheel is 33in.; there are 65 teeth in the spur wheel and 22 in the pinion, making the gear ratio 2·95. The tension of the line is 650 volts at the switchboard and 600 at the cars. The motors, made and installed by the General Electric Company, are rated at a maximum output of 52 h.p. at 500 volts, though in practice they are driven considerably beyond this, the maximum horizontal tractive effort actually exerted being 1,900lb. Series-parallel control is used. To compare the weights of the cars in the two cases, we may note that each motorcar on the Burgdorf Railway weighs 32 tons and carries 66 passengers, giving 1,070lb. per passenger.

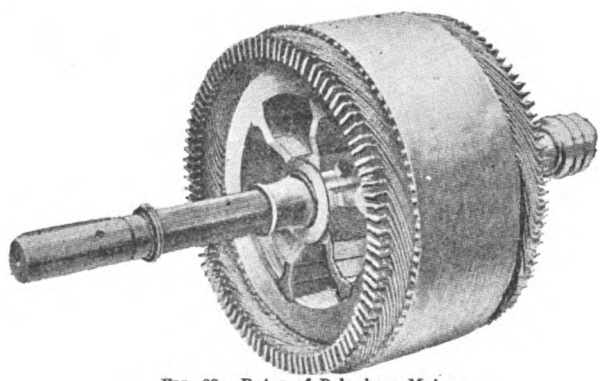


FIG. 23.—Rotor of Polyphase Motor.

Each car on the Chicago Railway weighs 18·2 tons and has seats for 40 passengers, giving 1,020lb. per passenger, so that there is but little difference between the two equipments in this respect. A complete series of tests was made at Chicago on Sept. 3, 1898, and is described fully in the paper referred to above. The results of two of these tests, which are typical of the rest, have been inserted in Table II., while the curves are given in Fig. 26 It will be seen that the continuous-current equipment can get up a speed of 23 miles per hour with 34·7 watt-hours per ton in 30 seconds, as compared with 41·5 watt-hours in 28 seconds with the three-phase equipment. Similarly, the continuous-current motors get up 24 miles per hour with 39·5 watt-hours in 37 seconds, as against 45·1 watt-hours in 30 seconds for the three-phase motors. Thus, for the lower speed, the continuous-current motors use 84 per cent. of the energy used by the three-phase motors, while for the higher speed the proportion is 87 per cent., while in the latter case the three-phase motors get up full speed in 81 per cent. of the time taken by the continuous-current motors. The reduction of energy in the continuous-current motors is due to the use of the series-parallel controller (compare Fig. 30). Comparing the maximum power input in the two cases, it will be observed that the power curves of the continuous-current equipment show a maximum of 150 kw. for two motors, or 75 kw. per motor, as against 53 kw. per motor in test No. 8 with the three-phase equipment. In some of the tests made at Chicago the maximum input reached 90 kw. per motor, but this was because the controller was not properly handled. The large majority of the tests gave 75 kw. as the maximum power input. It thus appears that the maximum power input as obtained in actual practice with the three-phase motor is only 70 per cent. of that with the continuous-current motor.

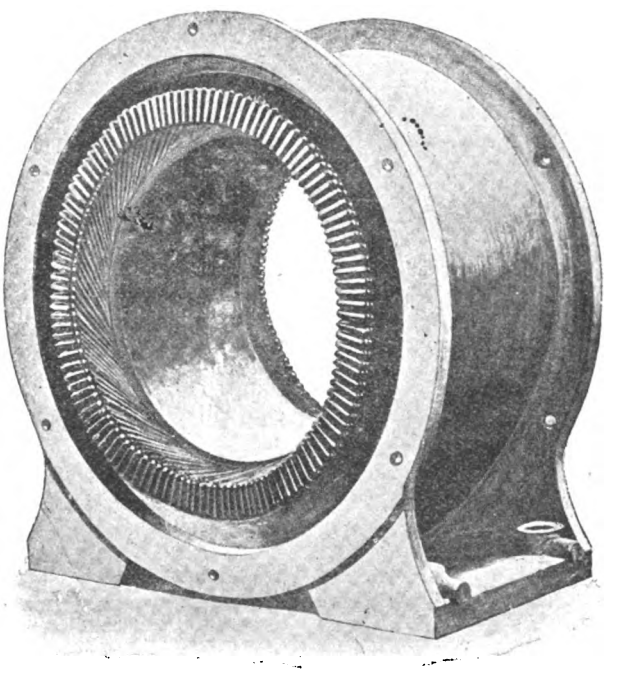

FIG. 24.—Stator of Polyphase Motor.

Conclusion.—The tests described above were made with the object of ascertaining the ability of polyphase motors to get up speed under ordinary conditions of railway service, and the economy obtainable in so doing when compared with that observed with the best continuous-current motors. The results of the tests go to show that polyphase motors are admirably adapted to getting up speed, and that the acceleration can be maintained uniform up to full speed. A comparison of the results with those obtained with one of the best and most complete continuous-current equipments shows that there is very

Digitized by Google

little difference between the two in economy of starting. The continuous-current motors have a slight advantage in the amount of energy expended, while they occupy a longer time in reaching high speeds, and require larger maximum power inputs than the polyphase motors. The author wishes to record his indebtedness to the following gentlemen for assistance rendered during the

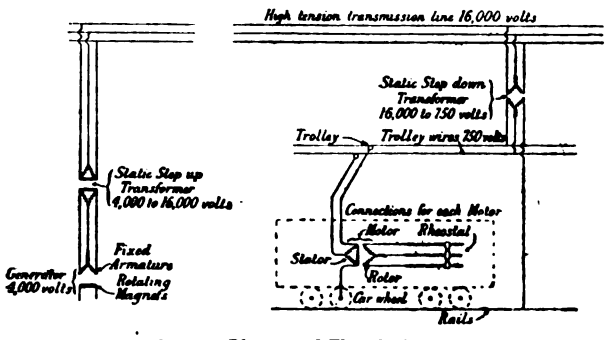

FIG. 25.—Diagram of Electric Circuits.

tests: Mr. K. Krähenbühl, engineer of the Burgdorf-Thun Railway; Dr. E. Blattner, professor at the technical college at Burgdorf; Messrs. E. Thomann, J. Landolt, H. Morgenthaler, and M. G. S. Swallow, engineers at Messrs. Brown, Boveri, and Co. He would also like to express his thanks to the firm of Messrs. Brown, Boveri, and Co. for the kind way in which they have provided him with data and information, and also to the management of the Burgdorf-Thun Railway, who afforded every facility for making the tests.

APPENDIX A.—*The Polyphase Motor.*

The action of a polyphase motor may be likened to that of a continuous-current motor, in which both the fields and the armature are capable of rotation. Supposing the fields of such a motor to be fully excited, and rotating at full speed with the armature at rest, a current of any desired

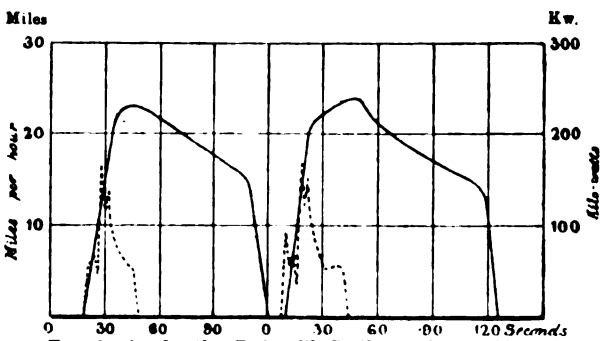

FIG. 6.—Acceleration Tests with Continuous-Current Motors.

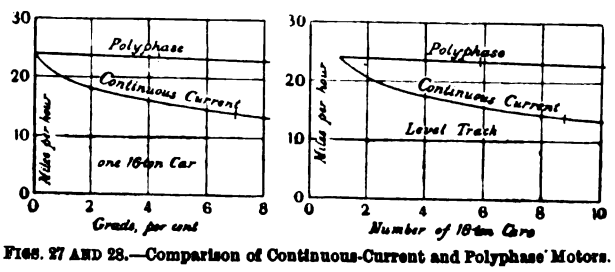
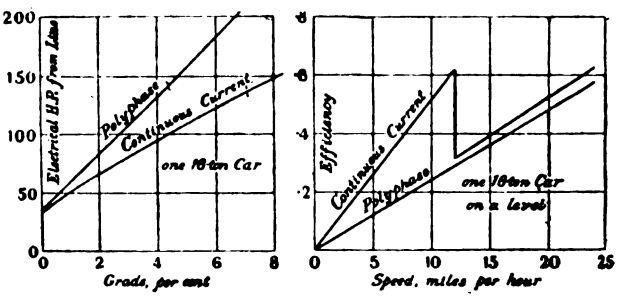
magnitude may be induced in the armature by simply short-circuiting it, since the generation of a current depends simply on the relative motion of the fields and the armature. The torque produced by the action of the fields on the induced current will tend to turn the armature, and if the fields be kept rotating at a uniform rate, the armature will speed up until the relative motion of the fields and the armature is sufficient to generate a current that exactly balances the load; uniform speed has then been reached. The slip, or the difference between



FIGS. 27 AND 28.—Comparison of Continuous-Current and Polyphase Motors.

the speed of the armature and the speed of the fields, is generally stated in per cent. of the speed that would be reached if the load were nothing—that is, if the armature were rotating at the same speed as the fields. This speed is spoken of as the speed of synchronism. In a polyphase motor the rotation of the field is produced by magnetising the fixed part, or stator, by two or more alternating currents in such a way that the resultant magnetic field rotates at a uniform speed. In the motors used on the Burgdorf Railway three alternating currents are used, differing in phase by 120deg. One great advantage of such a motor over the continuous-current motor is found in the absence of a commutator, for the current in the armature, or, as it is called, the rotor, can



FIGS. 29 AND 30.—Comparison of Continuous-Current and Polyphase Motors.

be induced by short-circuiting its coils through a simple form of slip-ring, the current from the line being led directly into the stator without any moving contacts. Fig. 23 shows the rotor and Fig. 24 the stator of a 150-h.p. polyphase motor.

Clearance.—In a polyphase system the ratio of the current usefully employed to that generated, as measured

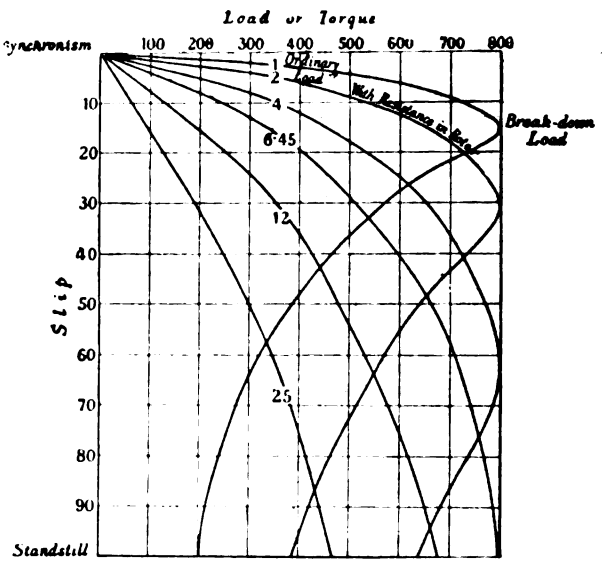


FIG. 31.—Load Curves of Polyphase Motors.

by the power factor, depends mainly upon the width of the space between the fixed and moving parts of the motor. Hence it is of great importance to reduce the clearance to the smallest limit consistent with safety. Thus the 64-h.p.

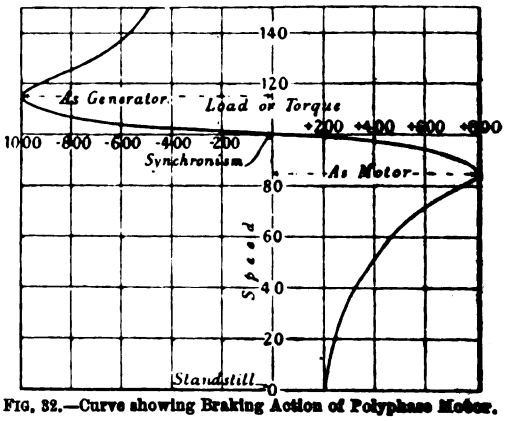

FIG. 32.—Curve showing Braking Action of Polyphase Motor.

motors on the Burgdorf Railway have a clearance of 1·5mm. on a radius and the 150-h.p. motors have a clearance of 3mm. This necessitates very careful construction, and special precautions have to be taken to prevent any chance of contact between the rotor and the stator. Figs. 6 to 9 give the details of the construction of the 150-h.p. motors on

Digitized by Google

the Burgdorf Railway. Some mechanical engineers consider the necessity of such a small clearance to be a fatal objection to the use of polyphase motors on railways, but experience shows that such motors can be constructed to run continuously without accident.

Variation of Speed with Load.—In a polyphase motor the speed is practically independent of the load. Thus the 64-h p. motors on the Burgdorf Railway run at full load with a slip of only 1·8 per cent. This is in marked contrast to the action of a continuous-current series-wound motor, such as is generally used on electrical railways, in which a reduction of speed of 40 per cent. from no load to full load is not uncommon. Figs. 27 and 28 show the speed variation of the Burgdorf motor compared with that of a standard continuous-current motor, firstly with constant load and varying grade, secondly with level track and varying load. The polyphase motor maintains the speed at the expense of a corresponding amount of power, while the continuous-current motor economises power at the expense of speed, as shown in Fig. 29.

Maximum Load.—In Fig. 31 is given the variation in speed from standstill to synchronism of a polyphase motor with different loads. Following the curve marked 1, it will be noticed that as the load increases the speed gradually decreases, until for a load of 300, for instance, the slip is 2 per cent. As the load still further increases the speed falls off in a greater ratio, until the maximum load of 800 is reached, where the slip is about 15½ per cent. This is the breakdown load. If the load be increased beyond this the motor cannot recover itself, and is brought to a standstill. In practice the maximum working load should not exceed 50 to 60 per cent. of the breakdown load.

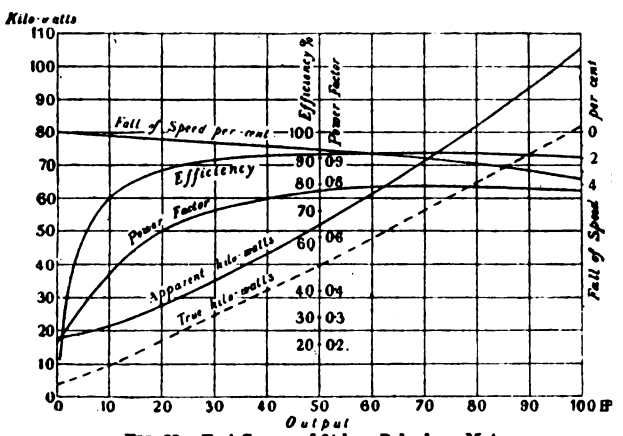

FIG. 33.—Test Curves of 64-h.p. Polyphase Motor.

Thus in the Burgdorf motors the maximum working load is 1·8 of the normal.

Speed Regulation.—If a resistance be placed in the circuit of the rotor so as to increase the total resistance, say to double it, the action of the motor will be represented by the curve lettered 2 in Fig. 31, in which the slip for equal torque is double what it was with the original resistance. The maximum torque is the same as before, but takes place with a slip of 31 per cent. instead of 15½ per cent. Thus with any load any required speed can be obtained by merely altering the rotor resistance. The polyphase motor is therefore capable of perfect speed regulations for all loads. The efficiency at reduced speed is, of course, less than that at full speed on account of the heating of the rheostats. The polyphase motor herein resembles the continuous-current motor, but it is at this disadvantage, in comparison, that it is not possible to couple two polyphase motors together in the way that two continuous-current motors can be coupled in the series-parallel method of control. The superiority of the continuous-current motor in this respect has, however, been somewhat overstated, seeing that is only for speeds less than half of full speed that the motors can be put in series. This point is illustrated by Fig. 30, which gives the comparative efficiency at equal load and different speeds of a polyphase and continuous-current equipment. For heavier loads the advantage of the latter would be reduced.

Action when Descending a Grade.—The speed curve No. 1 in Fig. 31 is reproduced in Fig. 32, and continued in order to show the action of a polyphase motor when driven above synchronism—as, for instance, when a train is descending a grade. It will be seen that as the speed increases above synchronism a negative torque is applied, and the motor acts as a generator, returning current into the line, and thereby retarding the motion precisely as if mechanical brakes were being applied. The maximum torque that can be thus applied is greater than its breakdown torque as a motor, but the slip at the maximum torque is the same. This is a feature of great importance, for not only does the polyphase motor act as an efficient brake in descending a grade, but the energy of the descent is returned into the line and is available for driving other trains. Thus, on the Engelberg Railway, which is a mountain railway worked by polyphase motors, the trains descend a 25 per cent. rack grade held only by the brake action of the motors, which keeps the speed at 4 per cent. above synchronism. Part of the current delivered into the line drives another train up a 5 per cent. grade, the remainder being used up in a rheostat.

Starting.—From Fig. 31 it will be seen that there is a certain rotor resistance corresponding to standstill with maximum torque, in this case 25 times as much as the resistance of the rotor itself. If the rotor resistance has this value at the moment when the motor is connected to the line, it will start with its maximum torque. If the resistance is taken out of the circuit as the motor speeds up, the torque can be maintained constant and equal to the maximum starting value up to full speed for that load. In other words, the torque, and therefore the acceleration, can be maintained constant practically up to full speed. It follows that the speed curve of a train driven by polyphase motors shows uniform acceleration up to full speed. Compare the speed curves given in Fig. 19.

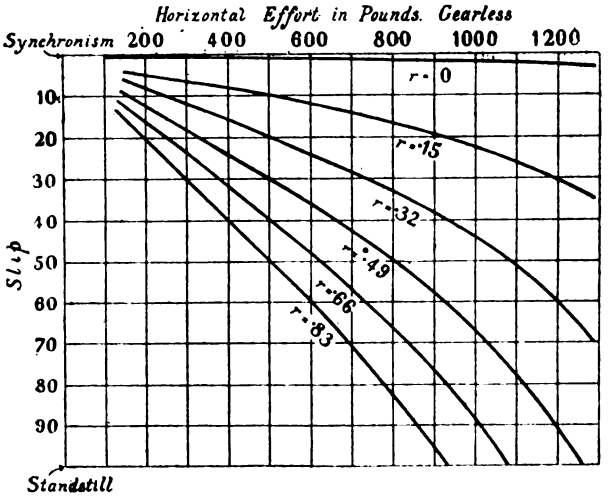

FIG. 34.—Load Curves of 64-h.p. Polyphase Motor

APPENDIX B. — *Particulars of the Motors used on the Burgdorf Railway Motorcars.*

The stator winding consists of 51 turns per phase, and is connected up in mesh. When hot, the short-circuited resistance of the winding per phase is 0·71 ohm. The rotor winding consists of eight turns per phase, and is connected up in star, the short-circuited resistance per phase being 0·0135 ohm hot. The characteristic features of the motors are well shown by the curves given in Fig. 33. These were obtained by brake tests made with motors of the same type as those used on the Burgdorf Railway, and differing from them only in the width of the clearance, which was 1·25mm., as compared with 1·50mm. in the Burgdorf Railway motors. Owing to the low internal resistance the speed is very uniform, the slip at full load being only 1·8 per cent. For the same reason the efficiency at full load is high—namely, 92 per cent. The large value of the apparent watts at no load indicates a large magnetising current, amounting to 24 amperes or, 28 per cent. of full-load current. The good efficiency at full load, however, shows that the wattless component is a more important element in the magnetising current than the hysteresis component; in other words, that the pre-

Digitized by Google

dominant factor in accounting for the large no-load current is the width of the clearance. This is further evidenced by the rapid rise of the efficiency curve, giving relatively good efficiencies at light loads. The large wattless component also influences the form of the power-factor curve, making it rise very slowly at first and reach its maximum at about full load. The wider clearance in the Burgdorf motors will, of course, influence the form of the power-factor curve, lowering it throughout its length. Hence the values of the true watts obtained by taking the power factors given in the curve sheet will be too high. This must be borne in mind when the results of the tests are considered.

APPENDIX C.—*Coasting Tests with Polyphase Motors.*

In Fig. 22 are given the automatic speed curves obtained by bringing a single motorcar up to full speed and then allowing it to coast, with the current cut off, before applying the brakes. The data of these tests are given in Table III.

TABLE III.—Coasting Tests on the Burgdorf Railway. One Motorcar of 32 Tons.

GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE SCIENTIFIC SOCIETY.

At an ordinary meeting of the above society on the 15th inst., the president, Mr. David Home Morton, M.I.C.E., in the chair, Prof. Alexr. MacLay, B.Sc., M.I.M.E., read a paper on "Technical Colleges in Germany." In the early portion of his paper Prof. MacLay outlined the preliminary training of the young German, which compared fabourably with Board schools in this country. Passing from this primary school, the student entered the middle school, and from this to real schools (Realschulen), the latter giving a higher education similar in many repects to the modern side of many of our own schools. Proceeding, the professor dealt more particularly with technical high schools, and sketched briefly the educational courses through which the student had to pass. In most cases they were modelled on lines similar to the technical colleges in our country—viz., a thorough grounding in pure science during the first and second year, gradually changing to a more specialised course. During the latter portion of a student's college career practical work in the laboratory, and such experimental work as had a direct bearing on the professional career of the student, formed the major portion of a session's work. Students generally spent 36 to 45 hours per week, starting at 8 a.m., and sometimes 7 a.m, while in this country the hours at similar institutions are 30 or 35, and fees generally for day classes 50 per cent. higher. Evening instruction was conspicuous by its absence. Not only were the necessary subjects, such as chemistry, mathematics, mechanics, steam, electricity, etc., taught, but budding engineers, chemists, and electricians attended lectures on political science, jurisprudence, hygiene, and similar subjects. These, although not entirely neglected in the technical institutions of our own country, did not form part of the recognised course of study for the diploma, although their importance was probably quite as great in producing a man of sound judgment. Proceeding to deal with the equipment and staff of these institutions, Prof. MacLay showed many slides showing the interior of the classrooms and laboratories, many of which rivalled, and not a few seemed to excel, similar institutions in our own country. Electrical engineering seemed in many of the more important colleges to have become a separate section, and great attention was devoted to it. In one of the colleges the author had seen an electric crane of 2½ tons capacity, fitted with three motors, used for lifting the heavy machines in the engineering laboratory. The teaching staffs of these colleges was remarkable, not only in respect of their professional status, but in numbers. One college had in the department of metallurgy and chemical technology no less than 41 teachers; other schools had in similar departments numbers varying from 12 to 40, depending on the size of the town and the nature of the local industries. Great attention was paid to what was being done in other countries; as an instance, the library of the school at Aachen had 250,000 specifications of English patents on its shelves.

An interesting discussion took place, at the close of which Prof. MacLay was awarded a hearty vote of thanks for his valuable paper.

PROMPT DELIVERY AND ERECTION.

English manufacturers have not a good name for prompt delivery, and it is no uncommon thing to hear of promises broken. It is, therefore, refreshing to hear of an electric lighting station in this country which placed an order for a 500-kw. steam alternator at the end of November, and had it running in time to take part of the Christmas load. This is the case of the Sheffield Corporation, who, on Nov. 28 last, acting on the advice of their chief engineer and manager, Mr. S. E. Fedden, decided to purchase one of Parsons steam turbo-alternators to help them over the Christmas load. The order was, therefore, sent off by telegram to Paris, where the machine was still standing in the position it had occupied throughout the exhibition. It was immediately taken down, packed, and dispatched to Sheffield, and on Dec. 21 it was running with 200 amperes at about 12 o'clock noon. This machine was no light weight to be taken by passenger train, as it weighed some 14 tons. It was of Messrs. C. A. Parsons and Co.'s 500-kw. capacity type.

Besides the plant, the question of steam and exhaust mains had to be promptly taken up. Thus the 16in. exhaust mains and steel riveted steam mains were ordered as soon as the drawings could be made out, and were delivered in about 17 days. When they came to be erected in the turbine, they were found to fit accurately. The steam and exhaust piping was supplied by Messrs. Tasker's Engineering Company, of Sheffield. We agree with Mr. Fedden in his opinion that great credit is due to both these firms for the smart and able way in which the whole of the work referred to has been carried out. At the same time a large share of the credit should be given to Mr. Fedden himself.

LIGHT RAILWAYS.

With regard to the proposed light railway to Arkholme, we learn that the appeal to the landowners in the county of Westmoreland to subscribe £10,000 having failed, the scheme has been practically abandoned.

At a recent private meeting of the Bridlington Town Council it was decided to oppose the application of the promoters of the proposed light railway from Bridlington to Flamborough for an extension of time for commencement of the construction of the works until March, 1902. The Council are contemplating an expenditure of about £10,000 in the widening of Clough Bridge, and the opponents of extension maintain that no practical benefit will accrue if after the widening of the thoroughfare the railway lines are laid down. It is said that the railway promoters have voluntarily offered to contribute towards the cost of widening the road.

A committee has been appointed by a recent meeting of the villagers of St. Combs and Charlestown in connection with the order obtained for the Fraserburgh and St. Combs light railway. A Treasury grant of £5,000 has been obtained. Mr. Charles Buchan, St. Combs, has been appointed convener, and Mr. Archibald Strachan secretary to the joint committee.

An application has been made to the Board of Trade to extend the limit fixed by the Ramsgate light railway order by two years as far as sections Nos. 4 and 8 are concerned.

The promoters of the Tanat light railway from Llangynog to Oswestry have received an intimation from the Treasury that the free grant will be increased by £10,000. The capital

Digitized by Google

required is not wholly made up, but there is every probability that it will be forthcoming shortly. In the case of the proposed light railway from Welshpool to Llanfair, the free grant has also been augmented by £7,500. All the capital is now guaranteed.

Last week the Lord Chancellor, Lord Macnaghten, Lord Shand, and Lord Robertson dismissed the appeal *re* Wallasey United Tramways and Omnibus Company *v.* Wallasey Urban District Council, and the *Morning Post* says that lawyers appear to be in agreement that the decision of the House of Lords in the above most important case governs the action of the Reading Tramways Company, Limited, *v.* the Corporation of the Borough.

The Commissioners have intimated to the promoters that they hope to submit the order authorising the Blackpool and Garstang light railway to the Board of Trade for confirmation before the end of this year.

We notice that the Flamborough Parish Council have received an application for an extension of time for the completion of the Flamborough and Bridlington light railways.

A public meeting of the inhabitants of Dingwall was held recently to express appreciation of the services of Mr. Arthur Bignold, of Lochrosque, M.P. for the Wick Burghs, by whose instrumentality or influence a Treasury grant of £33,000 and a loan of £4,500 have been promised towards the Dingwall and Cromarty light railway scheme.

A report has just been submitted to the Glamorgan County Council asking them to assent to a resolution which, if adopted, will commit them to a scheme of considerable magnitude. The motion reads as follows: "That in the opinion of this Council it is desirable that tramways, or light railways in the nature of tramways, upon the roads in the county, shall be owned by the County Council or by district councils, and that the Parliamentary Committee be instructed to employ skilled advisers to prepare a scheme of the lines that may be advantageously promoted for the consideration of the Council. That until the Parliamentary Committee is reconstructed, in accordance with the new standing orders, a representative of each parliamentary division that is not now represented thereon be added to it for this purpose."

The Whitehaven Town Council have appointed a committee to report on the application for the order for the West Cumberland light railway. There appears to be some difficulty on account of the proposal to take powers to supply electric light within the Council's area, and also in regard to the purchase of the undertaking.

The Spen Valley light railway order and the Spen Valley light railway order (extensions) came before the Board of Trade on the 14th inst., on objections raised to their confirmation by the Corporation of Batley and the Urban District Councils of Heckmondwike, Liversedge, and Gomersal, and the Great Northern Railway Company. The promoters of the two light railway schemes are the British Traction Company. The Spen Valley light railway proposes to run from Cleckheaton, through Liversedge and Heckmondwike, and then over the hill to Dewsbury, and from there on to Ravensthorpe. The extension scheme is to go from Liversedge up to the Pack Horse and round to Cleckheaton, making a circuit; and there is another proposed branch from Liversedge, through Gomersal to Birkenshaw, to join the Bradford tramways. Sir C. Boyle said he should advise the Board of Trade, as to the extension order, to accept the order of the Light Railway Commissioners, but to make it absolutely clear that the powers of construction given (the light railway company should not commence until the owers of the Corporation entirely lapsed. As regarded Halifax-road, he would advise the Board that the preamble was proved, and that the Spen Valley light railway should be granted. He left open the exact terms of the running powers, but said the order should authorise the construction of the Board of Trade line and its user, subject to regulations which may be approved by the Board. The matter was subsequently discussed, and finally it was agreed that the Corporation should construct the lines, with running powers to be mutually agreed upon between the light railway and the Corporation, and in case of disagreement as to the exact terms, they were to come before the Board again. The order was settled accordingly.

At the last meeting of the Loughborough Town Council the Town Clerk reported that, acting on instructions, Alderman Bumpus and himself had obtained an interview and discussed with the secretary of the Light Railway Commissioners the representations he (the town clerk) had formally lodged on behalf of the Corporation with the Light Railway Commissioners with respect to the Loughborough and district light railway order, as proposed to be issued by the Commissioners, owing to the alterations or omission therefrom of the agreed amendments and additions for the protection of the Corporation, and, as a result, a number of further alterations had been provisionally made in the proposed order, though not in every case in the manner sought by the Corporation, and a number of other points required settling. After the explanatory statement by the town clerk, it was resolved to approve of the action taken so far, and to instruct the Parliamentary Sub-Committee to continue their efforts for securing such provisions in the order as will meet the requirements of the Corporation.

The Commissioners have addressed a communication to the Middlesex County Council on the subject of the light railways joint order promoted by the Council and the Metropolitan Tramways and Omnibus Company, Limited, and the agreement between the two parties. The letter states that upon consideration of the arrangement and the various difficulties in the way of giving effect to it, and also of the advantage, as the Commissioners conceive it, of settling this order directly in accordance with the course which it is practically determined to follow as soon as the order is confirmed, the Commissioners are of opinion that the powers of the intended order should be given direct to the County Council, the agreement between the parties holding good in all other respects in the same way as with the Middlesex (No. 2) order. After due consideration of the question, and hearing the views of the company's representative, the County Council has resolved to agree to the suggestion made by the Commissioners for the order to be issued to the County Council alone, and to enter into a further agreement with the company to meet the altered position of affairs. The effect of this is to place the County Council in the same position as if it had exercised the option of purchase provided for by one of the clauses in the agreement with the company.

At the enquiry last week into the application of the Southwold Railway Company for an extension of their line from Southwold to Kessingland, and the widening of the present system between Halesworth and Southwold, the Commissioners reserved their decision.

At the last quarterly meeting of the Glamorganshire County Council a resolution was adopted to the effect that it was desirable that tramways upon the roads in the county should be owned by the County Council or by district councils, and that the Parliamentary Committee be instructed to employ skilled advisers to prepare a scheme of the lines that may be advantageously promoted for the consideration of the Council.

The Board of Trade have recently confirmed the following light railway orders: (1) Gosforth and Ponteland Light Railway Order, 1900, authorising the construction of a light railway in the county of Northumberland and Ponteland; (2) Wotton-under-Edge Light Railway Order, 1900, authorising the construction of a light railway in the county of Gloucester, between Wotton-under-Edge and Charfield; (3) Rhyl and Prestatyn Light Railways (Extensions) Order, 1900, authorising the construction of light railways in the parish and urban district of Rhyl, in the county of Flint, in extension of the light railway authorised by the Rhyl and Prestatyn Light Railway Order, 1900.

PRACTICAL COLOUR PHOTOGRAPHY.

A number of gentlemen attended at the Queen's Hall last week, by invitation of Mr. Robert Newman, to view specimens of what were called natural-colour-photograms prepared by the McDonnough process. They consisted of reproductions of landscapes, and copies of paintings, portrait studies, and various inanimate objects. The portraits especially were all that could be desired, and their colouring was, if anything, even better than that of the landscapes. Some of the latter did not show to their best advantage, as the operator was handicapped by a very inefficient lamp. The exhibition proved that these beautiful and very lifelike photographs can be obtained with extremely rapid exposures, and, according toMr. C. N. Crewdson, who explained the views taken by him at Oberammergau, the manipulation of the process is perfectly easy even to the veriest amateur. The process consists of a combination of Ive's three-colour system of Prof. Joly's diffraction grating. Owing to the labours of the late Mr. McDonnough and Mr. D. K. Tripp, the way of taking these photographs has become a very simple one. All that is necessary is to obtain a screen, which consists of a plate of glass ruled alternately with fine parallel red, green, and violet lines. Of course, the negative shows no colour, but from it a positive transparency can be obtained, which by means of the same screen will give a picture in natural colours. The practical value of the process and one which can be hardly over estimated, consists in the fact that by its means coloured prints on paper may be obtained by methods of ordinary photography, and for larger editions of books, etc., by photo mechanical means by the aid of the printing press. The architect can, therefore, obtain accurate representations of stained glass windows, and with regard to this matter we notice that the views in which windows were introduced were entirely free from halation, and consequently beautiful representations of rooms, theatres, etc., lighted by electricity ought to be obtained by it. This would be a great help to those interested in the introduction of electric lighting where its advantages are not known. It will also effect an enormous saving of time and expense to manufacturers, as the traveller in ceramic ware, or carpets, or wall paper, or any other manufactures where it is indispensable that the true colours of the material should be submitted to the purchaser, can do all his business by exhibiting these photographs, instead of the tiles, vases, or whatever he deals in.

Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street London, E C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
nited Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Flee Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered price 8s. 6d.

THE END OF THE CENTURY.

If it be asked what is the most important topic for technical discussion at the end of the century, the answer will be the same as it was at the beginning of the century—prime movers. The progress of the century is due to two causes: (1) the increased perfection in locomotion due to steam, and (2) the celerity of transmission of news due to the developments in telegraphy. No doubt a great many would object to these views, and put as the cause of progress the spread of knowledge. We prefer to agree with Buckle ("Hist. Civ.," vol. i., p. 38), that knowledge is a result, and not in the first instance a cause; later on, however, knowledge accelerates progress. The indications at the close of the century point to still greater progress due to improvements in heat engines. There is an old axiom too often forgotten, that "Necessity is the mother of invention." The pinch of necessity has made it desirable to more largely utilise natural sources of power, and to obtain a greater conversion efficiency from a given expenditure of heat energy. Why else are so many schemes presented for the transmission of power over longer distances? The reason, of course, is greater efficiency; hence a lessening of cost to the consumer of energy. In the first instance transmission schemes contemplated the more economic use of existing apparatus, but within the past few days attention has been directed to great economies to be effected by using Mond producer gas and large gas-engines in power stations. Further, according to an American consular report, a gain of from 30 to 50 per cent. efficiency can be obtained from ordinary steam-engines. The exact words are: "Its economy may be realised from the fact that the exhaust steam from a 2,000-h.p. central-station engine should furnish power to drive an additional 1,000-h.p. engine, which can be connected as an extra cylinder to the steam-engine or run independently, and thus increase by 50 per cent. the power developed without adding a pound to the quantity of fuel consumed." Let us assume for the moment these improvements to be commercially practical. It is at once seen that even under conditions involving no further improvement than this, our coalfields receive a very long increase of life. Up to the present time the best central-station working requires at least "three pounds of coal per hour per average indicated horse-power." With the addition of the sulphurous acid apparatus, this would be reduced to two pounds of coal per hour, a quantity approximating to that used in good marine-engine practice. Of course, the ordinary central station uses a good deal more than this, but whatever be the quantity, the saving is immense. The question as to initial cost of apparatus and cost of maintenance presents no difficulty, and can in any special case be compared with the amount of one-third of the annual coal bill. It is more difficult to judge the true value of producer gas, but undoubtedly while it may prove of great use in the developing of large gas-engines, it will aid rather than displace the distribution of electric energy. Lastly, a cause

Digitized by Google

more detrimental to progress than any other is as rampant at the end as it was at the beginning of the century—it is ignorant legislation. Henry Bell devised the steamboat, he told his plans to Fulton, and with the latter carried out his plans in America, subsequently coming back to Glasgow and building the "Comet." The work of Bell in this direction is well recognised, but it is not so well known that he designed to introduce steam traction on common roads. His designs came to naught, and automobilism was retarded for a whole century because an ignorant Legislature would not permit the necessary high-pressure engines to be used. Perhaps, had the Legislature been wiser, railways would have developed differently—whether for the better is no use now to discuss.

To all Readers,

A HAPPY AND PROSPEROUS NEW CENTURY.

FORTHCOMING EVENTS.

SATURDAY, DEC. 29.

Royal Institution of Great Britain.—At 3 p.m., lecture on "The Earth and its Heat," by Sir Robert Ball.

TUESDAY, JAN. 1.

Royal Institution of Great Britain.—At 3 p.m., lecture on "The Evidence from the Stars," by Sir Robert Ball.

WEDNESDAY, JAN. 2.

Society of Arts.—Juvenile lecture in the afternoon by Mr. E. Walter Maunder, F.R.A.S., superintendent of the Solar Department, Greenwich Observatory, on "Eclipses."

THURSDAY, JAN. 3.

Civil and Mechanical Engineers' Society.—"The Case for Electrical Power Distribution," by Mr. W. B. Esson, M.I.C.E., M.I.E.E.

Rontgen Society.—At 8 p.m., ordinary meeting at 20, Hanover-square, W. Dr. J. H. Sequiera will show some cases of Rodent Ulcer treated with X Rays. Afterwards a paper on "Continental Progress in Practical Radiography and Apparatus," by Mr. A. W. Isenthal, will be read.

Royal Institution of Great Britain.—Lecture by Sir Robert Ball on "The Significance of Planetary Movements," at 3.

SATURDAY, JAN. 5.

Royal Institution of Great Britain.—"The Evolution of the Moon," by Sir Robert Ball, at 3.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

NERNST ELECTRIC LIGHT COMPANY.

SIR,—The criticisms made by Mr. Zusman at the recent meeting of the Nernst Electric Light Company, Limited, on me in my capacity as managing director of that company, have not unnaturally attracted interest and attention amongst my friends. It was arranged at the meeting that I would deal in detail at the adjourned meeting, in a month's time, with all these allegations, but in view of the interest which these remarks have created, as above mentioned, I would like to state that there is absolutely no foundation for any of the allegations, and that at the adjourned meeting of the company I shall have no difficulty in refuting them in the most complete and ample manner.—Yours faithfully,

BERNARD M. DRAKE.

82, Victoria-street, S.W., Dec. 20.

The above letter was also sent to the *Financial News*, which paper has received the following letter on the same subject:

"Sir,—My attention has been drawn to a letter in your issue of to-day from Mr. Bernard Drake, stating that it was arranged at the recent meeting of the company that Mr. Drake should deal with the allegations of Mr. Zusman at the adjourned meeting in a month's time. I was present at the meeting in question, representing a large number of shareholders, and I would remind Mr. Drake that it was distinctly arranged at that meeting that he should, without delay, lay his explanations before the shareholders by circular, so that they might have ample opportunity to consider them, and not wait until the holding of the adjourned meeting, as he now appears to contemplate.—Yours faithfully, AUGUST COHN.

15, Throgmorton-avenue, E.C., Dec. 22."

ON RAPID VARIATIONS IN THE CURRENT THROUGH THE DIRECT-CURRENT ARC.*

BY W. DUDDELL, WH.SC., ASSOCIATE.

(Continued from page 888.)

PART II.—CURRENT CAUSED TO VARY BY THE ARC.

Humming.—Mr. Trotter discovered that the direct-current humming arc rotates, including a coma-like appearance at the + crater, and he also found that the current through the arc varied periodically, the frequency of these variations being the same as the pitch of the humming sound produced and as the speed of rotation of the arc. In order further to investigate the connection between the variation of the light P.D. and the current, I have recorded the P.D. and current by means of an oscillograph, the humming arc experimented on being used as the source of light to illuminate the oscillograph mirrors. The arc was so inclined that only the light from the + crater and a small part of the vapour column reached the mirrors, so that the density at any point of the lines represents the photographic intensity of the light emitted at that instant in the direction of the mirrors by the + crater and part of the vapour column, and the distance of the point from this zero line measures the P.D. or the current as the case may be.† A typical example of the variations observed in the humming arc is given in Fig. 5, from which it will be seen that the P.D., current, and light emitted in a fixed direction vary in a regular periodic manner with the same frequency. The variation of the current, which is about 6 per cent. from the mean, is not sufficient to account for the large variation in the light emitted in the direction of the mirrors. This periodic variation of the light is most probably due to the fact that the arc rotates, so that the + crater alternately either supplies light to the oscillograph mirrors, or is prevented from doing so by being on the other side of the + carbon. The periodic time of the variations of the light will, of course, be unaffected by a change in the position from which the arc is observed, but the times at which the light maxima occur relatively to the times at which the current is a maximum will depend on this position. Thus, besides the rotation of the humming arc and the variation of the current observed by Mr. Trotter, I find that the light and P.D. vary with the same frequency, so that in the humming arc the frequencies of the rotation of the arc, and of the variations in the P.D., current, and light emitted in a given direction, are identical with the pitch of the note given out.

Hissing.—It has been shown by Messrs. Frith and Rodgers, and by Messrs. Duddell and Marchant, that when a direct-current arc supplied from a constant source hisses, the current through it and the P.D. between its terminals vary rapidly, and M. Blondel and Mr. Brown have also found that the light emitted varies. If the current through the humming arc be increased until the arc hisses, the variations in P.D., current, and light change, I find, in a most striking manner from the regular periodic variations of Fig. 5 to the very irregular variations shown in Figs. 6 and 7. In spite of the very irregular nature of the variations, which irregularity is not surprising in view of Mrs. Ayrton's explanation of the cause of hissing given before this Institution last year, I think that they can be separated into two kinds—a large comparatively slow variation, and a rapid superimposed one. The light given out is alternately bright, with rapid variations in intensity, *a* to *b* (Fig. 6), and dull with hardly any variations, *b* to *c*; the slow variation of the light corresponding with the larger variation of the current; the maximum light and current do not, however, occur simultaneously. In view of the explanation given in the case of the humming arc that the large variations of the light is due to its rotation, and in view of the fact that the hissing arc is also probably rotating, as pointed out by Mrs. Ayrton, I think that the larger variations of P.D., current, and light in the hissing arc must also be due to the rotation of the arc. If this is the case, then the brighter parts

* Paper read before the Institution of Electrical Engineers.

† In Figs. 5, 6, and 7 the centre line is not the zero line, but represents 20 amperes and 40 volts.

Digitized by Google

of the curves are produced by light from the + crater and the rapid variations of density chiefly present in these parts of the lines are due to the rapid variation of this light from the + crater. [Experiment.] Now, these rapid variations in the light correspond with the small rapid changes in the current and the P.D., so that the rapid variations of P.D. and current correspond with the variations of the light emitted by the + crater, and the large slow variations with the rotation of the arc as a whole. Considering one of the larger light maxima, say from *a* to *b*, or *c* to *d*, Fig. 6, during which the oscillograph mirrors receive the light from the + crater without being obstructed by the carbon, it will be seen that in many cases the maximum light and minimum P.D. occur practically at the same instant, whilst the maximum current occurs later than the

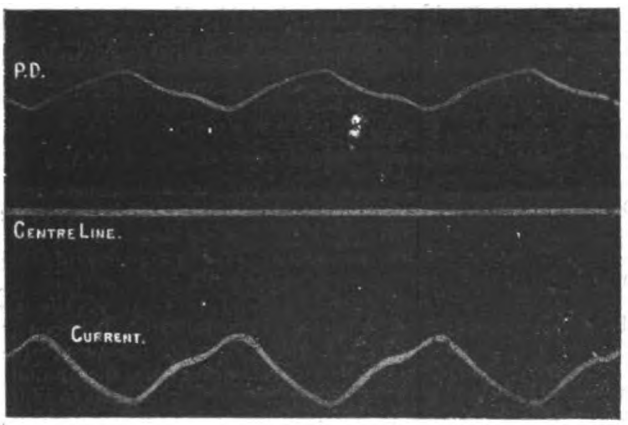

FIG. 5.—Humming Arc. Carbons +11 and −9 mm. Solid "Apostle." Mean P.D. = 50·5 volts. Mean current = 15·2 amperes. Scales: 1mm. = 0·5 volt = 0·186 ampere = $\frac{1}{640}$ second. Centre line = 40 volts = 20 amperes.

light maximum. This is the opposite to what occurs when the current through the arc is varied by any change in the circuit, for in this latter case the maximum current occurs before the light maximum. The periodically recurring sequence of events in the hissing arc is thus probably as follows, putting aside the rotation of the arc as a whole. Owing to the crater becoming too large for the end of the + carbon, the air obtains access to the crater surface as found by Mrs. Ayrton, the oxygen of the air there combines with the carbon, causing a rise of temperature, an increase of brilliancy, a drop in the P.D., followed very slightly later by a rise in the current. I think that the above observations on hissing and humming are explained by, and confirm, the fundamental nature of Mrs. Ayrton's discovery of the cause of the hissing of the arc.

Sounds Emitted by Very Short Arcs.—A very short hissing arc, so short that practically no light can get out from between the carbons, sometimes produces a shrill whistling sound, accompanied by a small tongue of green flame. The variation of P.D. and current for such an arc are given in Fig. 8, in which the current and P.D. have varied between two limits—viz., 22·5 amperes at 24 volts and 28 amperes at 9·5 volts—the former of which would produce a hissing arc, while the later values of the current and P.D. can only be explained on the assumption that the arc is short-circuited by a bad contact, such as a loose piece of carbon. The whistling sound is probably due to the periodical short-circuiting and relighting of the arc.

Sounds Emitted by Very Long Arcs.—The frying sounds emitted by very long arcs, noticed by Mrs. Ayrton, are probably due to the fact that long arcs are very sensitive as telephone receivers, as mentioned in Part I., so that very slight variations in the current will cause them to give out sounds. In confirmation of this it may be mentioned that a very long silent arc can be obtained if the arc is supplied with current from accumulators which are not in use for any other purpose, and if the arc circuit be so arranged that no variations of the current can be induced, or produced, in it by causes outside the arc. If, on the other hand, the direct-current arc be supplied by a dynamo, or if the arc circuit be placed so that there is mutual induction between it and leads carrying a dynamo current, then the long arc will give out a sound corresponding with rate at which the dynamo segments pass the brushes. This explanation was, I believe, first suggested by Prof. Ayrton and Mr. Mather.

Intermittent Arcs.—If a direct or alternate current arc be blown out by means of a jet of air or CO_2, or by means of a transverse magnetic field, it will, under suitable conditions, relight itself; and if the blowing be continued, the arc will be extinguished and relight itself again and again with great rapidity, giving out a harsh sound. The rapidity of these intermittances may be very great; M. Blondel has found them to be as high as 3,000 to 4,000 per second in the case of the alternate-current arc, and M. Abrahams has obtained 100,000 per second in the case of the same discharge. It was suggested by Prof. Fitzgerald that this intermittance of the arc might be used to produce some high-frequency alternating current which I required. I therefore tried rendering a direct-current carbon arc in series with a self-induction intermittent by means of a magnet. With this arrangement the rate of intermittance was irregular and not very high, probably owing to the E.M.F. of my source of supply being too low, although E.M.F.'s up to 300 volts were employed. In order to try and overcome this irregularity, I connected a condenser (about five microfarads) between the terminals of the arc, when to my surprise I found that the direct-current arc was intermittent even when not blown in any apparent way either by a stream of gas or by a magnetic field, and, further, that no self-induction in series with the arc was necessary. Here, then, was a puzzle—a direct-current solid arc burning under ordinary conditions with resistance in series, and supplied with current from accumulators, became intermittent and gave out a musical note on simply shunting the arc with a condenser. Leads were, of course, employed to connect the condenser as a shunt to the arc, and on twisting these leads together so as to destroy the small amount of self-induction which they possessed, I found that the musical note stopped, to be started again on separating the leads; and on interposing in the condenser circuit a loose coil of wire, the sound was greatly magnified. Hence the true statement of the facts is that given below.

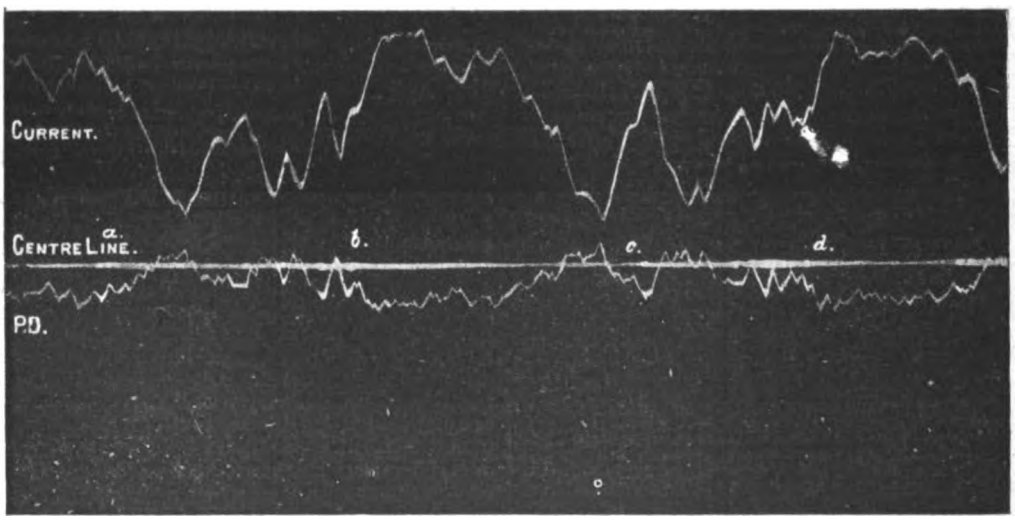

FIG. 6.—Hissing Arc. Carbons +11 and −9 mm. Solid "Apostle." Mean P.D. = 38 volts. Mean current = 22·3 amperes. Scales: 1mm. = 0·5 volt = 0·1 ampere = $\frac{1}{640}$ second. Centre line = 40 volts = 20 amperes.

Musical Arc.—A direct-current arc of suitable length and current, between solid carbons, will give out a musical note if it be shunted with a condenser in series with a self-induction, as in Fig. 9, even though the source of supply of the current be perfectly constant and the arc be protected as far as possible from any outside cause of disturbance. [Experiment.] I find that the musical note is produced by oscillatory currents flowing in the circuit composed of the condenser, F, the self-induction, L, and the arc (Fig. 9), and its pitch is determined

Digitized by Google

by the periodic time of this circuit—that is, on the relation between the capacity, self-induction, and effective resistance of the circuit. Neglecting the resistance, which it will be shown later must be small, the periodic time of the circuit $\tau = 2\pi\sqrt{L.F.}$, and this has been found, by judging the pitch of the note by ear, to be approximately correct, so that for lecture purposes Kelvin's law can by this means be easily demonstrated. It must be remembered that, although we have an alternate current through the condenser and self-induction, the source of supply is not an alternating one, and that it is the arc itself which is acting as a converter and transforming a part of the direct current into alternating, the frequency of which can be varied between very wide limits by altering the self-induction and capacity. The upper limit I find to be about 10,000 ~ per second, and the lower limit, if such exists, is well below 500 ~ per second. It has long been known that a train of oscillations of almost any frequency can be obtained on discharging a condenser through a suitable inductive resistance, but, of course, these oscillations have a rapidly decreasing amplitude; and the means of supplying energy to such a circuit so as to maintain the amplitude of the swings constant, other than by means of a varying source of power having the same periodic time as the circuit, has been wanting. It is, therefore, necessary to enquire under what conditions it is possible for the arc to cause the source of direct current to supply the energy necessary to maintain the oscillations in the condenser circuit when once they have been started. If the resistance in the main circuit in series with the arc is large, and if the δ V be a small instantaneous change in the P.D. between the terminals of the arc, δ A the corresponding small change in the current through it, and r the resistance of the condenser circuit, not including the condenser; then, during the time this small change lasts, sufficient energy may be supplied to the condenser circuit to make up for the energy dissipated there, in ohmic loss, if the following conditions are fulfilled:

1. $\frac{\delta V}{\delta A}$, negative.
2. $\frac{\delta V}{\delta A}$, numerically greater than r.

The question is, Can the arc fulfil these two conditions? Messrs. Frith and Rodgers have experimentally determined the value of $\frac{\delta V}{\delta A}$, which they call the resistance of the arc, for various arcs, and they found that while $\frac{\delta V}{\delta A}$ was always + when both carbons were cored, it was, on the contrary, always − when both carbons were solid; and that it was as small as −2 ohms for a four-ampere solid arc. Now the resistance of the condenser circuit, r, external to the condenser can easily be made less than two ohms, so that the arc can fulfil both the necessary conditions. I will now describe some observations on the musical arc which tend to confirm the above conclusions. Arcs between solid carbons for which $\frac{\delta V}{\delta A}$ is always negative work well, while those between cored carbons for which $\frac{\delta V}{\delta A}$ is positive I find will not work under any conditions. [Experiment.] The largest negative value of $\frac{\delta V}{\delta A}$ given by Messrs. Frith and Rodgers is two ohms for a four-ampere solid arc, and it is probable that it did not exceed 2·5 ohms, for the smaller currents—viz., 3 to 3·5 amperes—which I used. According to the above conditions, 2·5 ohms should be the limiting resistance of the condenser circuit. By experiment it was found that when the resistance of this circuit was increased to 2·4 ohms, the oscillations stopped and could not be restarted. [Experiment.] It is evident that besides the resistance there are other causes, such as hysteresis, which tend to dissipate the energy in the condenser circuit and stop the arc giving its note. The hysteresis in an iron-wire core introduced into the self-induction will instantly stop the note. [Experiment.] Any complete circuit such as a ring of wire placed near the self-induction has the same effect. [Experiment.] On several occasions before the importance of these causes of the dissipation of the energy were realised, considerable trouble was experienced in tracing the reason of the arc failing to give its note. As examples, in one case it was traced to an ammeter and in another to the tinfoil in the condenser which were acting as short-circuited secondaries to the self-induction coil, which had been placed too near them. [Experiment.] The relation between the self-induction, capacity, and frequency can be very easily demonstrated by playing a tune on the arc by varying either the capacity or the self-induction by means of a keyboard. [Experiment.] Another method of varying the self-induction is by separating or bringing closer together the turns of the coil, as

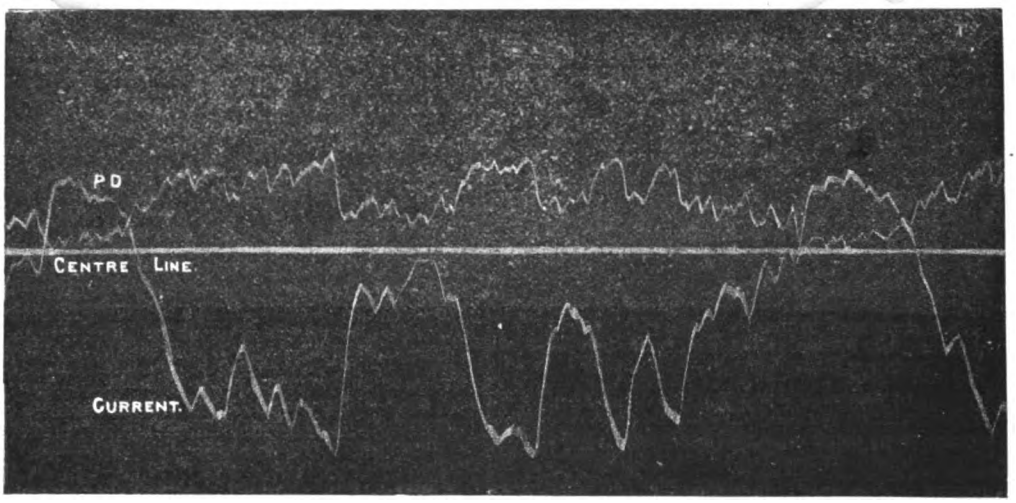

FIG. 7.—Hissing Arc. Carbons +11 and −9 mm. Solid "Apostle." Mean P.D. = 44·5 volts. Mean current = 19·5 amperes. Scale: 1mm. = 0·5 volt = 0·1 ampere = $\frac{1}{500}$ second. Centre line = 40 volts = 20 amperes.

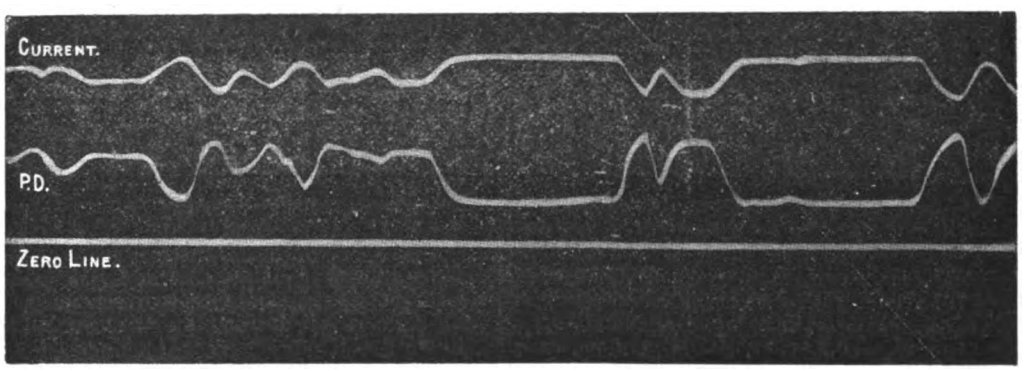

FIG. 8.—Very Short Hissing Arc. Carbons +11mm. cored "Apostle," −9mm. solid "Apostle." Scales: 1mm. = 1·5 volt = 1·0 ampere = $\frac{1}{500}$ second.

Digitized by Google

if playing on a concertina, the relative positions of the turns determining the self-induction and the pitch of the note. The musical arc can be used as a means of comparing self-inductions or capacities by comparing the pitch of the notes produced. The "enclosed arc" will work equally as well as the open arc, though the note given out is not so audible owing

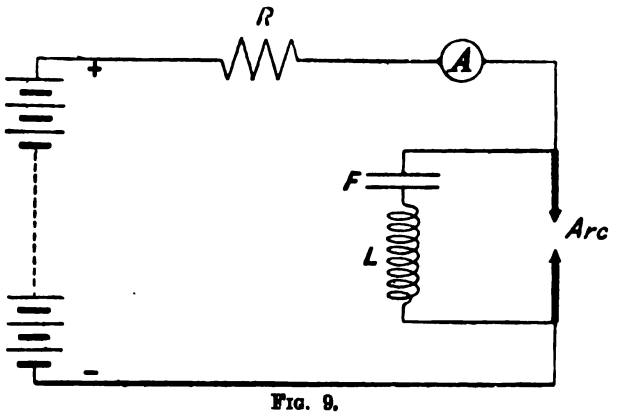

FIG. 9.

to the globe; but it can easily be made so by taking advantage of some of the telephoning effects mentioned in Part I.

(*To be continued.*)

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers.

QUESTIONS.

337. In a combined alternating and three-wire continuous-current station it is intended to couple the two systems by connecting an alternator direct to two continuous-current machines, which will be required to balance the three-wire system, supply the whole of the system on light load, or to drive the alternator and supply the alternating system at times of light load. Note.—The alternator is of the slow-speed type. Give diagram of connections.—L. B.

338. What are the requirements for a lightning arrester for overhead cables, and how far are these requirements fulfilled in the present instruments?—M.

ANSWERS.

Question No. 331.—Give method employed in calculating resistances for motor starters so as to get a certain number of amperes per contact. In liquid starters what is the usual current allowed per square inch of surface of iron plate electrode? Also give way of calculating resistance of liquid, say 5 per cent. soda solution.

Best Answer to No. 331 (*awarded* 10*s.*).—A resistance for a motor-starting segment switch is correctly designed when, at the starting up of the motor, the momentary rush of current over and above the normal as each section of the resistance is cut out must be the same.

To comply with these conditions, the values of the starting resistance in circuit with the armature must decrease at each step according to a proportional scale, or, in other words, the value of the resistance must decrease in geometrical progression. This difficulty is not met with in the design of liquid starters, as the resistance is decreased in perfect uniformity. In addition to the above requirements necessary for starting resistances, we very often find that a corporation or a supply company will demand that when motors are being put on to the mains, the current taken by the motor when the arm of the switch is on the first stop must not exceed, say, 10 amperes; so that if the normal current of the motor exceeds 10 amperes, we have to make the total starting resistance equal to $\frac{\text{volts on mains}}{10}$.

So that the portion of the resistance preceding the point at which the motor will take its normal working current is divided up into such sections that the value of the *current* increases in geometrical progression until it reaches the normal, and for the remainder of the resistance the current is constant, except for a momentary jump as each section is cut out.

It will probably make the above remarks more explicit if we take an actual case and deal with the design. For example, suppose we require a starting resistance for a 11½-b.h.p. motor, 220 volts and 1,080 revolutions per minute, the resistance being so arranged that the current when the switch arm is at the first stop is 10 amperes, and also that the jump of the current while switching on does never exceed 10 amperes (approximately).

Let us say the efficiency of our motor is 93 per cent. at full load, then the normal working current is—

$$\text{Normal current of motor} = \frac{11{\cdot}5 \times 746}{{\cdot}93 \times 220} = 42 \text{ (approx.)}.$$

We must also note that the resistance of the motor armature is ·153 ohm.

Then total starting resistance, including that of the armature,

$$= \frac{220 \text{ volts}}{10 \text{ amperes}} = 22 \text{ ohms}.$$

A portion of this 22 ohms is used to bring the current from 10 amperes up to the normal 42 amperes; the motor armature then commences to rotate (unless in special cases where a very large starting torque is needed), and the remainder of the resistance is cut out in bringing the motor up to its full speed.

Resistance required to give the normal current

$$= \frac{220 \text{ volts}}{42 \text{ amperes}} = 5{\cdot}5 \text{ ohms}.$$

Therefore 22 − 5·5 = 16·5 ohms. This part of the resistance is divided up into steps, so as to give the *current* increasing in geometrical progression, while the *resistance*, 5·5 ohms, is divided up in geometrical progression.

1. Current increasing in geometrical progression—

	Value of current.	Value of resistance in each step.	Steps.
1st point	10		
		$\frac{220}{20}$ = 11 ohms	1st
2nd point	20		
		$\frac{220}{30}$ = 7·33 ohms	2nd
3rd point	30		
		$\frac{220}{40}$ = 5·5 ohms	3rd
4th point	40		

The problem now is to divide 5·5 ohms up in decreasing geometrical progression so as to give the limiting jump in the current of 10 amperes. Let us say that the jump in the current can be kept low enough by cutting out the resistance in 16 steps. Now we commence by having a resistance of 5 5 ohms, and this is reduced in 16 steps down to the armature resistance, ·153 ohm. Therefore, we have to insert 15 geometrical means between 5 5 ohms and ·153 ohm, this being a simple problem in algebra.

Let r = the common ratio;

the 17th term = ·153 ohm—*i.e.*, the armature resistance;

$$\therefore \cdot 153 = 5\,5 \times r^{16}$$

$$\therefore r^{16} = \frac{\cdot 153}{5{\cdot}5} = {\cdot}002725$$

$$\therefore 16 \log r = \log {\cdot}002725.$$

$$16 \log r = \bar{3}{\cdot}436$$

$$\log r = \frac{\bar{16} + 13{\cdot}436}{16} = \bar{1}{\cdot}9 \text{ (approximate)},$$

from which $r = {\cdot}8$ (approximate).

Therefore, our resistances decrease as follows:

$$5{\cdot}5,\quad r\,5{\cdot}5,\quad r^2\,5{\cdot}5,\quad r^3\,5{\cdot}5\ \ .\ .\ .\ \ r^{17}\,5{\cdot}5,$$

Digitized by Google

and the value of the resistances in each step thus:

$5{\cdot}5 - r\ 5{\cdot}5 =$ 1st step;

$5{\cdot}5\ r - r^2\ 5{\cdot}5 =$ 2nd step, etc.;

$r^{16}\ 5{\cdot}5 - r^{17}\ 5{\cdot}5 =$ 16th step.

We can now tabulate our complete results:

Back E.M.F. of motor. $C = E - c(R_a + R)$	Drop of volts in armature and resistance. $C(R_a + R)$	Total resistance at any position of switch arm	Current.	Value current, momentary increases to.	Momentary jump of current	Switch points.

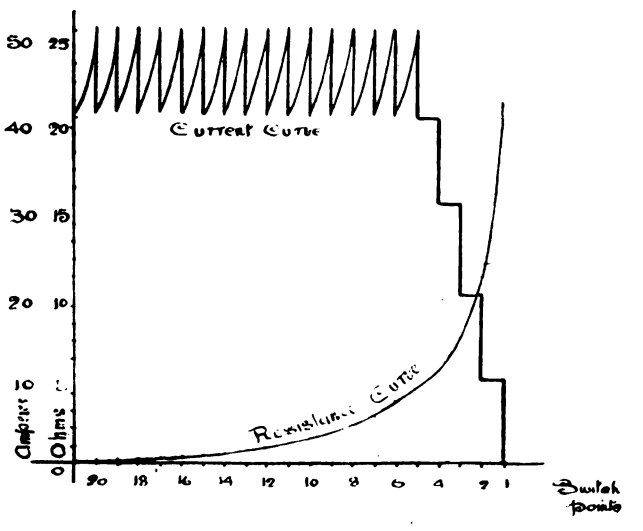
These tabulated results may now be plotted in the form of two curves, as below.



Current curve shows the rate of increase in the motor current on the first four points of switch, and also the momentary increases in the current as further steps are cut out, the armature having commenced to revolve.

The resistance curve shows the rate of decrease of the starting resistance with reference to the number of points on switch.

The above description, I think, covers any information required for the design of starting resistances, with the exception of fixing allowable sizes of wire for a given current, and as this can always be furnished by the maker of the particular kind of wire which you may decide to use, it is, I think, hardly necessary to touch on here. I may note that starting resistances may be graduated direct from the proportional scale of a slide rule. This will probably suggest itself to the reader.

With regard to liquid starters, the writer has found that a current density of 6 to 10 amperes per square inch of iron electrode surface to be a fair allowance for starting purposes. With reference to the resistance of a 5 per cent. soda solution, the writer does not know of any reliable method of calculating such a quantity. The usual way is to fix your current density and also your maximum distance between the plates, and then make up the percentage solution to suit your particular requirements.

The following figure is approximately correct for a 5 per cent. soda solution: two iron plates one square inch in sectional area and 1in. apart; resistance = 10 ohms (approximate).—H. P.

Answer to No. 331 (*awarded* 5*s.* 0*d.*).—The determination of the resistances between the successive contacts of a starting switch, so arranged as to preclude more than a certain sudden increase of current per step, falls into two parts dependent on different conditions and involving different considerations.

The first of these conditions obtains until sufficient current has been switched on to produce rotation. During this stage the resistances are in series with a circuit containing no counter E.M.F., and the current flowing is simply the supply voltage divided by the total resistance. In a shunt-wound motor the first contact or contacts will put in the exciting current, and the following steps augment that through the armature until sufficient torque to overcome the load and static friction flows. This quantity is somewhat greater than required whence once motion has begun. In a series motor, field strength and armature current, of course, increase together until the same torque is obtained. Let now V denote the supply voltage, C′ the current which may be suddenly drawn from the mains, and R_1 the total resistance of the switch and shunt. Then we must have

$$\frac{V}{R_1} = V\left(\frac{1}{R_2} - \frac{1}{R_1}\right) = V\left(\frac{1}{R_3} - \frac{1}{R_2}\right) = \text{etc.} = C'.$$

and consequently

R_1
$R_2 = \frac{1}{2} R_1$ } $\frac{1}{2} R_1$ = resistance between 1st and 2nd contacts
$R_3 = \frac{1}{3} R_1$ } $\frac{1}{6} R_1$ = " " 2nd " 3rd "
$R_4 = \frac{1}{4} R_1$ } $\frac{1}{12} R_1$ = " " 3rd " 4th "

$R_n = \frac{1}{n} R_1$, and generally resistance between the n-th and $(n \times 1)$-th contacts $= \frac{R_1}{(n \times 1)\, n}$.

This arrangement of resistances disposes of that portion of the switch connected with the shunt. The calculation now goes on at that point, where in the case of a series motor it begins, to the resistances in series with the armature. Until the machine begins to speed up the method of calculation is identical with the foregoing, the armature, or armature and series coils, resistance being taken in place of that of the shunt.

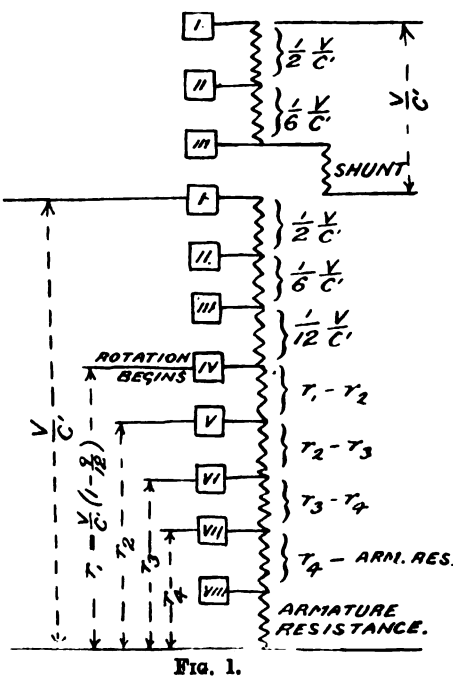


FIG. 1.

Let C denote the normal current for the load under which the motor starts up and runs, and let C_1 denote the starting current ($> C_1$, see above) reached at the n-th contact of this portion of the resistance. The second state of affairs mentioned is now reached. If, starting onward from this n-th contact, we denote the total resistances succes-

Digitized by Google

sively in circuit by r_1, r_2, r_3, etc., we have $r_1 = \frac{V}{C_1}$. The armature, however, now speeds up, producing a back E.M.F., v_1, and so reducing the current to C. The next step must, therefore, make r_2 such that $(V - v_1)\left(\frac{1}{r_2} - \frac{1}{r_1}\right) = C'$, or $\frac{V - v_1}{r_2} = C + C'$. The speed now again increases, bringing v_1 to some value, v_2, and thus $(V - v_2)\left(\frac{1}{r_3} - \frac{1}{r_2}\right) = C'$, and so on until after cutting out all the switch resistance the back E.M.F. has its full normal value. The point to be noted is that with a constant retarding torque, the motor will always speed up until its current is reduced to give an equal driving torque. Hence, if at the n-th contact a current, C_2, equal to or greater than C_1 was flowing, we find that:

At the n-th contact $r_1 = \frac{V}{C_2}$;

" $(n+1)$-th " $r_2 = \frac{V}{C + C'} - \frac{C_2 - C}{C + C'} r_1$;

" $(n+2)$-th " $r_3 = \frac{V}{C + C'} - \frac{C_2 - C}{C + C'} r' - \frac{C'}{C + C'} r_2 = \frac{C}{C + C'} r_2$;

" $(n+3)$-th " $r_4 = \text{etc.}, = \frac{C}{C + C'} r_3$;

" $(n+m)$-th " $r_{m+1} = \text{etc.}, = \frac{C}{C + C'} r_m$.

Thus $r_1 - r_2$, $r_2 - r_3$, etc., are the resistances between successive contacts (see Fig. 1).

As an example, let a shunt motor of ·17 ohm armature resistance, taking 50 amperes at its constant load, be considered. Starting current 55 amperes, supply at 200 volts, maximum sudden current increase 20 amperes. Here the shunt current would be well under the limit, and would be put on fully at the first contact. The second contact would start the armature current, and total resistance in must be $\frac{200}{20} = 10$ ohms. Thus

Resistance between 2nd and 3rd contacts $= \frac{1}{6}(10) = 5$ ohms.

" " 3rd and 4th " $= \frac{1}{6}(10) = 1{\cdot}56$ ohms.

The resistance in at the 4th contact is $10 - 6{\cdot}56 = 3{\cdot}44$ ohms, so that a current (C_2) of 58 amperes flows and rotation begins.

At the—

n-th contact, here the fourth, then		$r_1 = 3{\cdot}44$	1·97
5th	constant resistance in	$= \frac{200}{70} - \frac{58 - 50}{70} r_1 = 2{\cdot}47$	·7
6th	" " "	$= \frac{50}{70} \times 2{\cdot}47 = 1{\cdot}76$	·5
7th	" " "	$= \frac{50}{70} \times 1{\cdot}76 = 1{\cdot}26$	·35
8th	" " "	= etc. = 9	·25
9th	" " "	" = ·65	·19
10th	" " "	" = ·46	·13
11th	" " "	" = ·33	·09
12th	" " "	" = ·24	·07
13th	" " "	" = ·17	

Thus, since the armature resistance is ·17 at the 13th and last contact, the whole switch resistance is cut out. The resistances between successive contacts are given by the column on the right (calculated approximately).

As to the current density in a liquid starting resistance, the writer has found about four amperes per square inch work satisfactorily with the electrolyte mentioned (5 per cent. sodium carbonate). The limiting density depends upon either the rush of evolved gas being excessive, or upon the heating of the liquid. As ordinarily arranged, the latter limit is reached first, the electrolyte soon boiling and frothing over with a greater density than four amperes. Exact calculations for electrolytic starting resistances are almost impossible, however, as the permissible density in the liquid depends upon the length of time occupied in the machine's speeding up; also because the resistance varies enormously with the temperature, falling at 100deg. C. to less than half its value at 15deg. C., in the case of the soda solution.

The resistance of the quantity of liquid between two plates of the resistance is, supposing that the sectional area of liquid is not much greater than the area of the plate, equal to the (specific resistance × distance in inches plates are apart) divided by 2·54 (sectional area in square inches). The specific resistance—*i.e.*, the resistance in ohms per centimetre length of a column having one square centimetre sectional area—can in the case of a few solutions be found from tables. (Munro and Jamieson, however, give nothing, and there is more difficulty than there should be in getting this information.) In the case of the 5 per cent. soda—*i.e.*, 5lb. common washing soda ($Na_2CO_3.10H_2O$) in 100lb. of water—the specific resistance, as just determined by one in whom I put reliance, is 55 ohms at 15deg. C. There is, however, no simple rule for finding from this what it would be at another temperature or another percentage strength. The simplest rough method of ascertaining the resistance per inch length per square inch area is to fill a trough, b inches wide, to a depth c inches; place two electrodes a considerable distance a inches apart; send a current C amperes through, and measure the volts, V, across the electrodes. Then, neglecting polarisation, etc., we have

$$\text{Resistance per inch, etc.} = \frac{V}{C} \frac{bc}{a} \text{ ohms,}$$

A result sufficiently accurate for practical work—indeed, better than an accurate one, as it is determined under the working conditions for which the information is required.

In conclusion, one may perhaps suggest the desirability of placing under different numbers such distinct questions as are included under No. 331.—ZERO.

Answer to No. 331 (*awarded* 5*s.*).—The starting of a motor may be divided into two processes: (1) increasing its current by steps till it starts from rest; (2) increasing the volts on the armature till it reaches full speed. The first part is only necessary if the motor is on a lighting circuit, when pressure variations must be prevented at all costs; and as the resistance in each step can be at once determined by Ohm's law, we need not consider this part in detail. We will suppose that the motor is to start on full load, and that the torque to overcome that load is independent of the speed, as is usually the case; also that the full-load current passes when the switch is on the first stop.

Let C = full-load current;
Let R_1, R_2, R_3, etc. = total resistance in circuit (including the armature) when switch is on points 1, 2, 3, etc.;
Let E = supplied volts;
Let n = number of stops on starter;
Let R_a = resistance of armature;

$$R_1 = \frac{E}{C}.$$

$R_n = R_a$ = total resistance when switch is on last stop.

Now let switch be put on first point; the motor starts very slowly, so that its back E.M.F. is negligible; then

$$E = C R_1.$$

Now put switch on second point; then for an instant, before the armature can increase its speed and its back E.M.F., the total voltage round the circuit is $C R_1$, and the total resistance is R_2.

$$\therefore \text{current rises to } \frac{C R_1}{R_2},$$

falling again to C as the speed rises.

Then $E = C R_2 + \text{back E.M.F.}$

Now put switch on third point. For an instant the net forward E.M.F. is $C R_2$, and resistance is R_3.

$$\therefore \text{current rises to } \frac{C R_2}{R_3},$$

falling again to C as the speed rises.

Similarly, on stop 4, the current rises to $\frac{C R_3}{R_4}$. But our hypothesis is that the current is to rise to the same value on each stop.

Digitized by Google

$$\therefore \frac{C R_1}{R_2} = \frac{C R_2}{R_3} = \frac{C R_3}{R_4}, \text{ etc.};$$

that is, R_1, R_2, R_3, etc., are in geometrical progression. Our problem then resolves itself into finding n numbers in geometrical progression, the first being R_1 and the n th R_a.

$$\text{The common ratio } (r) = n\sqrt{\frac{R_a}{R_1}}.$$

This can easily be worked out with the help of logarithms; then R_1 being known, $R_2 = r R_1$, $R_3 = r^2 R_1$, etc. There is a simple mechanical method of getting these values by the aid of a slide rule almost without any calculation. The top scale of a 10in. rule is used, and it may be necessary to extend this scale to 15in. by means of the slide. We then have three similar 5in. scales, and figures on the first scale represent numbers one-tenth of those on the second scale and one-hundredth of those on the third scale.

Mark the armature resistance, R_a, on the first scale and the value of R_1 on the second or third scale as it happens to come. Now divide the distance between them into $n-1$ equal parts, and read off the figures at each point; these will be the values R_1, R_2, R_3, etc.

Resistance in first gap $= R_1 - R_2$.
Resistance in second gap $= R_2 - R_3$, and so on.

Starters are seldom made which really follow the law of geometrical progression described above, but the smoothness of starting thereby obtained, even with a comparatively small number of stops, is well worth a little arrangement.

In liquid starters a fixed current density at the surface of the iron plate should not be aimed out. One size starter will start one size motor, whether its voltage be 50 or 400. The difference should be made, not in area of plate, but in concentration of solution. The horse-power of the motor is the factor which determines the dimensions of the starter. One containing three gallons of suitable solution will start a 15-h.p. motor on full load without trouble.

It is not possible to calculate the resistance of a solution of stated concentration, because the resistance is no definable function of the concentration. The only way is to determine the resistance experimentally with varying strengths of solution, and plot a curve of specific resistance against percentage of solution. In a liquid starter, however, the best way is for the man who sets it up to add soda till he gets the most satisfactory result. Thus we get the most suitable arrangement for the actual working conditions, which can never be exactly foreseen, and this is one of the great advantages of liquid starters.—J. W.

Question No. 332.—In transmitting power to a distance, how does the load factor of the supply influence the commercial result?

Answer to No. 332 (*awarded* 7*s.* 6*d.*).—The commercial result of a transmission of power undertaking depends on the relation between the total annual income and the total annual expenditure. Taking the percentage dividend as the measure of the commercial result, we have

$$\text{D per cent.} = \frac{\text{Profits (annual)}}{\text{Capital}} \times 100.$$

Now, the capital does not in the least depend on the load factor, and may be taken as constant. It is therefore the profits with which we have to concern ourselves. The annual profits from a supply undertaking are equal to I – E, where I denotes the total annual income and E the total annual expenditure. Now, let F denote the load factor, which is the ratio between the total number of Board of Trade units generated in a given time to the maximum number of units which the whole of the generating plant could produce during that time. Let N denote the total possible output of the plant for a year in Board of Trade units; then

$$\text{I} = \text{price obtained per unit} \times \text{N} \times \text{F}.$$

The price obtained per unit, P, does not depend on F, but depends on the prices charged for steam, gas, or water power in the district supplied, as these competitive prices would determine the charge which could be obtained for electric power.

Now,
$$\text{E} = \text{cost of production per unit} \times \text{N} \times \text{F};$$
$$= \frac{\text{S} + (\text{G} \times \text{N} \times \text{F})}{\text{N} \times \text{F}} \times \text{N} \times \text{F};$$
$$= \text{S} + (\text{G} \times \text{N} \times \text{F});$$

where S = total standing charges per annum, consisting of interest on capital, depreciation, sinking fund, rents, rates, and taxes, salaries of officials, and all sundry expenses which do not vary with the number of units generated in the station. S is not dependent on the load factor. G denotes generating cost per unit, and may be taken as independent of F. Of course, in the case of long-distance transmission the loss in the line would be greater with a high load factor, as the cables would be working up to nearly their full capacity, and G would thus be increased. This cable loss would vary as F^2 (approximately). Although G would be increased owing to a loss of efficiency in the cables it would be decreased to an almost equal extent by increased efficiency of boilers, engines, dynamos, and station attendance, so for all practical purposes we may consider G independent of F, but of course dependent on the cost of coal (or whatever source of power is used), oil, repairs, maintenance, and attendance at generating station, and for distribution, if the latter is done at the supply undertaking's expense. We have, therefore,

$$\text{D per cent.} = \frac{\text{I} - \text{E}}{\text{capital}} \times 100$$
$$= \frac{(\text{P} \times \text{N} \times \text{F}) - \{\text{S} + (\text{G} \times \text{N} \times \text{F})\}}{\text{capital}} \times 100.$$

This formula denotes how the commercial result depends on the load factor. Of course, N × F is simply the total number of units sold per annum (F being calculated for a period of one year in above case), and it will be seen that this number varies directly as the load factor.—R. M. W.

Answer to No. 332 (*awarded* 5*s.*).—The cost of working a generating station consists chiefly of the following items: interest on outlay, coal, water, oil, waste, and stores, management expenses (salaries, etc.) and wages. These items may be divided into three classes: (1) those which are directly proportional to the maximum load on the station; (2) those which are directly proportional to the total yearly output; and (3) those which fall in between, being influenced both by the maximum load and by the total output. We will consider each item individually.

Interest on Outlay.—Seeing that the generating plant, the buildings to contain it, and the supply mains have to be put down for the maximum output, this item will be the same whatever the total output, and clearly belongs to case 1. It is sometimes supposed that this can be reduced by the use of accumulators, but as a battery for a given discharge rate costs more than a complete generating set for the same output, this is a mistake.

Coal.—This belongs to class 3. When the load is about to come on, fresh boilers have to get up steam, and a considerable amount of coal is wasted in the process; and when the load goes off again, these boilers are left full of hot water, representing wasted energy.

This may be minimised by the use of water-tube boilers, which hold only a small quantity of water and get up steam very rapidly. Another cause of poor economy of coal is that when the load is rising or falling, it is not possible to keep all the generators on full load, and their efficiency falls. This loss can be reduced by the use of accumulators, which permit all running plant to be kept on full load. Another partial remedy is the use of small units, but this partly defeats its own end, as small units are less efficient than large ones.

Water.—The question of reduced efficiency also affects the water bill, and it must therefore come under case 3, although it approaches more nearly to case 2 than does the coal.

Management.—The responsibility of managing a station of a certain size is independent of the total output; if anything, it is greater with a varying load, as the station hands need more supervision. The salaries of the manager and his assistants, therefore, come under case 1.

Wages.—If the station is a very large one the number of stokers, drivers, labourers, etc., will always be propor-

Digitized by Google

tional to the number of engines running. If the station is small, this will not be so, as one stoker, one driver, etc., must be present during the hours of light load, although not fully occupied. However, for the sake of argument, we will put it under case 2.

The most conclusive way of showing the influence of the load factor on the commercial results will be to take a reliable estimate of the cost per unit for a large station supplying a constant load day and night, and to apply the above considerations to determine the cost per unit with a given load factor. Let us take as a basis the figures given by Mr. Langdon in his paper before the Institution of Electrical Engineers, published in this journal last month. We will take a load factor of ·15, this being a fairly good figure for an English lighting station with a considerable motor load. The output of the station is 5,000 kw. The outlay includes mains and step-down transformers, and as the question gives no details, we can take this as being a typical scheme, but we will omit salaries of sub-station engineers and outdoor service men.

Column 1 gives the total cost per annum, and column 2 the cost per kilowatt-hour when working at a constant load of 5,000 kw., and columns 3 and 4 give the same when working at an average load of $5{,}000 \times \cdot 15 = 750$ kw.

Details of charges.	1. Per annum.	2. Per kilo-watt-hour.	3. Per annum.	4. Per kilo-watt-hour.
1. Capital outlay, £470,000.	£	d.	£	d.
Interest at 3½ per cent.	16,450 ...	·0901 ...	16,450 ...	·6000
2. Generating station :				
Salaries	1,320 ...	·0072 ..	1,320 ...	·0482
Wages	3.159 ...	·0173 ..	473 ...	0173
3. Coal	23,345 ...	·1279 ...	3 840 .. (say)	·1410 (say)
4. Water	913 ...	·0050 ...	144 ... (say)	·0052 (say)
5. Oil, waste, and stores...	2,000 ...	·0109 ...	300 ...	·0109
Total	47,187 ...	·2584 ...	22,527 ...	·8226

This shows in a very striking manner the disadvantage of working with a small load factor, and it also shows where the disadvantage principally occurs—namely, in the money lying idle in machinery which is standing for a large number of hours in the 24.—J. W.

LEGAL INTELLIGENCE.

THE WOLVERHAMPTON TRAMWAYS.

The case of the Mayor and Corporation of Wolverhampton *v.* the British Electric Traction Company was down on last week's list to be mentioned in the Chancery Division of the High Court before Mr. Justice Joyce.

Mr. Hughes, Q.C., who appeared on behalf of the Corporation, said his lordship would remember that this action was brought to enforce specific performance of a contract contained in an Act of Parliament for the sale of defendants' tramway undertaking in the borough of Wolverhampton to the Corporation, and was argued some few weeks ago. His lordship's decision was that the Corporation was entitled to specific performance, and that, in fact, was not really in dispute in the trial. The defendants, however, contended that they were entitled to running powers, and the question which now arose was as to whether interest was payable from the dates upon which the contract was to have been completed. The learned Registrar had stated that the question of interest could not be left open, owing to the form in which the judgment had been entered. He therefore asked his lordship to fix a day on which this point could be discussed.

Mr. Justice Joyce said he would hear the arguments on the following Thursday.

On the Thursday **Mr. Hughes, Q.C.**, for the Corporation, read at length the correspondence which had passed between the parties in reference to the sale, for the purpose of showing that they were entitled to 5 per cent. interest on £4 250, the amount of the purchase money. The Corporation forwarded a cheque for £4,250, and in reply a letter, written on behalf of the defendant company, was received, acknowledging the receipt of the letter and the enclosed cheque, and stating that the transfer would be executed without delay. Subsequently, the solicitor for the company telegraphed to the town clerk withdrawing the acceptance, but the Corporation insisted on the completion of the contract. The Registrar found some difficulty in drawing up the order and in dealing with the question of interest, which counsel said was a substantial sum. The statement of claim asked for an enquiry as to profits, but his friend, Mr. Freeman, had said that there had been no profits, and it was obvious that the enquiry would be a difficult one. He agreed that they could not have both profits and interest at the same time, and they preferred to take the interest and leave the profits alone.

Mr. Thompson, for the other side, contended that there had been no proper tender made.

His Lordship said he thought Mr. Hughes's clients were entitled to an enquiry.

After the argument, **His Lordship** made an order to the effect that the Corporation was entitled to 5 per cent. interest in lieu of compensation for the non-completion of the purchase from the date that the purchase money was tendered.—*Midland Counties Express.*

COMPANIES' MEETINGS AND REPORTS.

BLACKPOOL, ST. ANNES, AND LYTHAM TRAMWAYS COMPANY.

The second ordinary general meeting of the shareholders was held on the 19th inst., at Manchester, Mr. A. W. Carrington (Lytham) presiding over a large attendance.

The directors recommended a present dividend of 3 per cent. on the preference shares, leaving the payment of a further dividend of 2 per cent. on these shares over.

Mr. J. Fell (director) said he wished to explain that he objected to the payment of dividend on preference shares, because it had not, in his opinion, been earned.

Mr. Hengler (Hoylake) moved an amendment that the balance-sheet be referred to a future meeting to allow shareholders an opportunity of studying it in detail, but this was defeated on a vote, and the balance-sheet was adopted.

LONDON ELECTRIC OMNIBUS.

The report for the period of Nov. 30 states that the efforts of the present Board have been entirely devoted to the object of placing the Company in such a position so that a definite and feasible working scheme could be submitted to the shareholders. The future existence of the Company now depends upon the response received to the circular dated 18th inst. This circular states that, in the opinion of the directors, electricity as applied to street traction (except as regards tramways) has not been developed sufficiently to warrant their advising the shareholders to experiment further with it, but they consider that a system of street cars capable of carrying 14 passengers could be made a success. If a sufficient number of shareholders agree, it is proposed to reconstruct the Company, the shareholders receiving one £1 share in the new Company for every share held in the old Company, the new shares having a liability of 5s. per share.

NEW COMMITTEES.

The following appointments have been made :

BATH.—*Electric Lighting* : Alderman Taylor, chairman.

BERMONDSEY.—*Electric Lighting* : Councillor Cox, chairman.

HAMMERSMITH —*Electricity and Lighting* : Alderman Glasier, chairman ; Councillor Bendon, vice-chairman.

HEYWOOD.—*Electric Lighting* : Alderman Maden, chairman.

KING'S LYNN (NORFOLK).—*Electric Lighting* : The Mayor ; Aldermen Miles and Jermyn ; Councillors Affleck, Carpenter, Chatterton, Floyd (chairman), and Miles.

KINGSTON.—*Electric Lighting* : Alderman Collings, chairman.

NEWBURY – *Electric Lighting* : Mr. J. Rankin (mayor), chairman.

STRATFORD UPON AVON.—*Electric Lighting* : Councillor Holtom, chairman.

WALSALL – *Tramways* : The Mayor (Councillor W. J. Pearman-Smith) chairman ; Councillor Powell, vice chairman. *Electric Lighting* : Councillor Brownhill, chairman ; Councillor Noake, vice-chairman.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Asuncion (Paraguay).—The Municipality invite tenders for the installation of the electric light in the town. Tenders by Jan. 15, 1901.

Madrid.—The Department for Agriculture, etc., invite tenders for the installation and working for 60 years of an electric tramway from Insepets to Fogas and Boranova. Tenders by Jan. 7, 1901.

Hendon.—The Urban District Council invite tenders for the supply and erection of various plant for the municipal electricity works. Tenders by Dec. 31. Details in our advertisement columns.

Edinburgh.—The Corporation invite tenders for the extension (about 100 lamps) of the electric lighting installation at the City Chambers. Tenders by 31st inst.

Ayr.—The Corporation invite tenders for the work required in forming permanent way, rail-laying, roadwork, etc., of about 5¾ miles of electric tramways. Tenders by 10 a.m. on Jan. 4.

Southampton.—The Corporation invite tenders for the overhead electrical equipment of about 1¾ miles of tramway route. Tenders by Jan. 7, 1901. Details in our advertisement columns.

Digitized by Google

Farnworth.—The Urban District Council invite tenders for eight 66 passenger tramcar bodies, motors, undertrucks, controllers, etc. Tenders by Jan. 10. Details in our advertisement columns.

Glasgow.—The Corporation invite tenders for the supply of telephone apparatus in connection with the Glasgow Corporation tramways. Tenders by Jan. 18, 1901. Details in our advertisement columns.

Salford.—The Tramways Committee invite tenders for tie-bars, fishplate bolts, etc. Specifications, etc., may be obtained from Mr. Ernest Hatton, tramways engineer, Town Hall, Salford. Tenders by Dec. 31.

Battersea.—The Council invite tenders for the supply of ordinary and prepayment electricity meters, in accordance with specification No. 10. Tenders by Feb. 1, 1901. Details in our advertisement columns.

Partick.—The Corporation invite tenders for the construction, supply, and erection of steam dynamos, battery-charging motor, booster, and balancer. Tenders by Jan. 7. Details in our advertisement columns.

Middleton.—The Corporation invite tenders for superheaters, economisers, feed pumps and pipes, tanks, steam and exhaust pipes, valves, and accessories. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Rathmines.—The Electric Lighting Committee invite tenders for the supply and erection of various plant for the extension of the municipal electricity works. Tenders by Jan. 10, 1901. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for the supply of condensing plant and cooling tower, secondary battery, mains switchboard, and travelling crane. Tenders by Feb. 1, 1901. Details in our advertisement columns.

Farnworth (Lancs.).—The Urban District Council invite tenders for steel girder tramrails, fishplates, etc. Drawings may be seen from the engineer, Mr. W. J. Lomax, A.M.I.C.E., 11, Fold-street, Bolton. Tenders by Jan. 8, 1901.

Worthing.—The Corporation invite tenders for the supply and erection of a main switchboard. Specifications, etc., can be obtained from Messrs. Burstall and Monkhouse, 14, Old Queen street, Westminster, S.W. Tenders by Dec. 31.

Whitby.—The Urban District Council invite tenders for erection of an electric light station and destructor. General conditions, etc., can be obtained on and after Jan. 1 from the Clerk at the offices of the Council, Whitby. Tenders by Jan. 8.

Belfast.—The Harbour Commissioners invite tenders for 10 tramway trucks, each capable of carrying a weight of 10 tons on a 3ft. gauge. Further information may be obtained from the harbour engineer, Mr. G. F. L. Giles. Tenders by Jan. 7.

Turin (Italy).—The Public Works and Artillery Department in this town require tenders for 20 tons of copper ingots, to be delivered within 40 days of acceptance of tender. The provisional deposit is £1,840, the final deposit being 10 per cent. of the total. Tenders by Jan. 7.

Tooting.—The Metropolitan Asylums Board invite tenders for the execution of certain wiring and other works in connection with the proposed electric light installation at the asylum now in course of erection at Tooting Bec. Tenders by Jan. 2, 1901. Details in our advertisement columns.

Rotherham.—Tenders are invited for the supply of electricity meters of sizes for maximum currents of 5, 10, 20, 25, and 35 amperes. The supply pressure is 230 volts, continuous current. Tenders should be sent to Mr. H. Hampton Copnall, town clerk, Council Hall, Rotherham, by Jan. 19, 1901.

Thetford (Norfolk).—The Town Council invite tenders for supplying the wiring and fittings necessary for the electric lighting of the new town hall according to plan and specifications, which can be seen at the office of Mr. John Houchen, town clerk, London-road, Thetford. Tenders by Jan. 1, 1901.

Poplar.—The Borough Council invite tenders for the supply of an electric crane to lift a maximum load of five tons, with a return block, the electricity supply being continuous current at 460 volts. Specification, etc., may be obtained from the Borough Electrical Engineer, at the Electricity Works, Glaucus-street, Bromley-by-Bow, E. Tenders by Jan. 16, 1901.

Leeds.—The Lighting Committee invite tenders for electric lighting plant as follows: (Section A) two sets, each comprising engine of 2,000 b.h.p., two-phase alternator of 1,400 kw. capacity, and exciter; (B) two sets of surface-condensing plant. Specifications, etc, may be obtained from Mr. Harold Dickinson, manager of the department, 1, Whitehall-road, Leeds. Tenders by Dec. 31.

Manchester.—The Manchester Ship Canal Warehousing Company, Limited, invite tenders for the supply, delivery, and erection of 22 electric jib cranes required for work at the new transit shed, No. 8 dock, Manchester. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, M.I.C.E., chief engineer to the company, 41, Spring-gardens, Manchester. Tenders by Jan. 4.

Winwick (near Warrington, Lancs.).—The Committee of Visitors for the County Asylum invite tenders for (Contract No. 3) wiring, etc., including ring main and feeders, sub-main, lamp circuits, switchboards, distribution boards, fittings, etc. The drawings, etc. can be inspected at Winwick Hall, and also at the offices of the architects, Messrs. Crisp and Oatley and W. S. Skinner, Edinburgh-chambers, Baldwin-street, Bristol. Tenders by Dec. 29.

Worthing.—The Electric Lighting Committee invite offers from any person, firm, or company willing to instal, equip, and maintain a system of electric tramways in the borough, with power to the Corporation to acquire the same at any specific date upon agreed terms, such offers to specify the price to be paid for current to be supplied from the central station of the Corporation electric lighting works. Tenders by Dec. 31.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Scholen. Tenders must be received by Jan. 15, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

Wolverhampton.—The Tramways Committee invite tenders for the supply of the necessary materials and labour for the construction of tramway track and contingent works in Tettenhall-road, New Hampton-road, Waterloo-road, Darlington-street, Queen-square, Lichfield-street, Fiveways, Piper's-row, Bilston-street, Cleveland road, and Bilston-road to the borough boundary, amounting to a route length of about 4½ miles, mainly double track. General conditions, etc., may be seen at the office of Mr. J. W. Bradley, M.I.M.E., borough engineer and surveyor, Town Hall, Wolverhampton. Tenders by Jan. 15.

RESULTS OF TENDERS.

Aldershot.—The tender of Messrs. Parker, of Wolverhampton, at £14 466, has been accepted for the laying down of an installation of the electric light for Aldershot.

Brighton.—The Council have accepted the tender of Messrs. Macartney, McElroy and Co., Glasgow, at £102,487. 14s. 5d., for the construction of the tramroads, and the laying of certain routes with wood.

Hampstead.—A contract has been entered into with Messrs. W. Neil and Co. for construction of boiler foundations, flues, and enclosure to economiser in north boiler-house at the electric station extension at £3,094. 4s. 6d.

Swansea.—Eight tenders have been received for the supply of meters, etc., and the resident engineer has been authorised to order supplies from Venner and Co., the General Electric Company, and the British Thomson-Houston Company.

St. Pancras.—The Guardians have received 18 tenders for the installation of electric lighting in the Cook's-terrace infirmary. The estimated cost was £500. 6s. The whole of the tenders, which ranged from £471 up to £1 600, have been referred to the Housing Committee for consideration, consultation, and report.

Croydon.—The tender of the Wheeler Condenser Company, Limited, for an additional Bernard cooling tower, at £758, is recommended for acceptance. The Tramways Committee have accepted the tender of Messrs. James Smith and Sons, Limited, for the erection of the Brighton-road car shed, at £3,145.

Greenwich.—The Guardians have received the following tenders for electric lighting at Grove Park Workhouse:

Pearson and Co., London	£7,550
F. Troy and Co., London	7,374
National Electric Wiring Company, London	7,350
Hampton and Sons, London	6,598
Barlow Bros. and Co., London	6,400
Drake and Gorham, London	6,380
Geipel and Lange, London	6,278
S. G. Cozens, Brockley	6,140
Collins Bros., Blackheath	5,921
Foote and Milne, London	5,763
Johnson and Phillips, Charlton	5,550
H. F. Joel and Co., London	5,456
R. Dawson and Co., Stalybridge	5 014
Lea and Warren, Kettering	4 910
G. F. Cook and Co., Lightcliffe	4,338

BUSINESS NOTES.

LIGHTING AND GENERAL.

Hastings.—The Town Council intend to apply for sanction to borrow £276 for extension of mains.

Bath.—Claverton-street is to be lighted by electricity at a cost of £150 for cable and £240 for six arc lamps.

Stratford upon-Avon.—Application has been made to the Board of Trade for an electric lighting provisional order.

Dorchester.—The Town Council have sealed the memorial to the Board of Trade relative to the electric lighting of the borough.

Ludlow.—Mr. Enright will shortly visit the town to confer with the Electric Light Committee on the plant supplied by him for electric lighting.

Hampstead.—Additional mains for the supply of electric current to private consumers are to be laid in Cannon-hill, Platt's-lane, and Belsize-park-gardens.

Teddington.—The District Council have sealed a memorial to the Board of Trade in support of the application for an electric lighting provisional order.

Shildon.—The Urban District Council last week sealed the agreement with the Northern Counties Electrical Supply Company for the electric lighting of the district.

Digitized by Google

Share Market.—There was little doing in electric shares during the past week, but the tone kept good; almost the only bargains consisted of the squaring up of the account.

Mitcham.—The Croydon Rural District Council have applied for a provisional order to supply electricity for all public and private purposes throughout the parish of Mitcham.

Ripon.—In their application for an electric lighting provisional order the Corporation seek powers to establish electrical works and supply their own electricity at a capital outlay of £15 000

Epsom.—The Urban District Council have decided to apply for sanction to borrow £2,793 as an extension of the loan of £16 100 already obtained for carrying out the electric lighting installation.

Reduced Tariffs.—The Eastern Telegraph Company have given notice that reduced tariffs will be brought into operation on Jan. 1 for Cape Colony, Natal, the Transvaal, Orange River Colony, and Rhodesia.

Eccleston.—The Chester Corporation are conferring with the agent of the Duke of Westminster as to the question of the laying of mains for supplying Eccleston with electric light, the estimated cost being £3,480.

Retford Hospital.—Preliminary steps are being taken for the erection of the proposed new wing at a cost of from £500 to £600. An offer of £150 has been received for an accident ward and Röntgen-ray room.

Woolwich.—The London County Council have approved a loan of £20,000 (first instalment of £86 658), repayable within 42 years, for electric lighting and dust destructor works within the borough upon certain terms.

Wireless Telegraphy.—Trials of the wireless telegraph are to be made at Inishtrabull, Ireland, to report vessels. Arrangements have also been made for night as well as day signalling at Kildonan, Arran, Scotland.

Aldershot.—The District Council have decided to lay down an installation of electric light at an estimated cost of £20,000. Application is to be made to the Local Government Board for sanction to borrow this sum.

Indiarubber Culture.—It is stated that the Department of Agriculture have set aside the islands of Panay and Panitani in the Iolo Islands for the cultivation of indiarubber, as the American supply of the gum is failing.

Dover.—The electric light company being prepared to negotiate for purchase by agreement, the Corporation have now resolved not to proceed with their Bill, but have asked Mr. Manville to report with a view to the negotiations.

Bingley.—At the meeting of the District Council last week it was decided to dissent from the proposed Electric Power (Yorkshire) Bill, 1901. A statutory meeting of ratepayers is to be held to approve or otherwise of the Bingley Bill.

Handsworth (Staffs).—At the ordinary meeting of the Town Council, held on Dec. 12, permission was granted to the National Telephone Company to lay pipes for underground wires along Birchfield-road and World's End-road under agreement with the Council.

Obituary.—As we go to press we regret to hear of the death of Lord Armstrong, C.B., LL.D., D.C.L., F.R.S. This occurred shortly after one o'clock yesterday morning at Craigside, Rothbury. A full notice of the work done by the deceased engineer will appear in our next issue.

Luton.—The Reason Manufacture Company, Limited, have approved the draft contract for the supply of Wright's patent demand indicators. The draft contract for the supply of Aron meters has been forwarded to the General Electric Company, Limited, for approval.

New Firm.—We are informed that the combined businesses of Laing, Wharton, and Down, Limited (acquired from the Receiver), and J. S. Cunnington and Co., will henceforth be carried on by them at 93, St. Martin's-lane, W.C., under the style of Laing, Wharton, and Cunnington.

Aylesbury.—At a special meeting of the Urban District Council it was resolved to apply to the Board of Trade for an extension of time, and in the meantime to treat for land and ascertain companies willing to undertake the work in connection with the electric lighting of the town.

St. Austell.—The Council have consented to the application of the St. Austell and District Electric Lighting and Power Company, Limited, for a provisional order under the Electric Lighting Acts in place of the order now subsisting and known as the St. Austell Electric Lighting Order, 1894.

Removal.—Messrs. Doherty and Donat, engineers, licensees for Zschocke's patent water-cooling towers, and agents for Blake and Knowles's pumps, etc., have removed to larger premises at 82 and 83, Deansgate-arcade, Deansgate, Manchester, where they will keep samples of their specialities.

Gloucester.—The Corporation have decided to enter into an agreement with Messrs. Sisson and Co. for granting them facilities for carrying out specified tests of engines and generating plant, and as to affording a supply of electricity at the works of Messrs. Sisson for power purposes.

Coventry.—The Corporation have now fixed upon the following scale of charges for electrical energy for motive power: for any quantity up to 100 units per quarter per kilowatt demanded, 6d. per unit; for any quantity consumed beyond such 100 units per quarter per kilowatt demanded, 1d. per unit.

London Gazette.—A first and final dividend of 1s. 7½d. per pound has been declared in the estate of W. Haines, 261, Bury New road, Whitefield (Lancs.), payable at Official Receiver's Offices, Exchange-street, Bolton, from Dec. 27.

Ham.—The Richmond (Surrey) Electric Lighting Supply Company have decided to charge consumers 6d. per unit, and in consequence the District Council have agreed that part of the resolution which makes the consent of the Council as conditional on the maximum price being fixed at 6d. be rescinded.

Newbury.—At the last meeting of the Council the Mayor reported that the Board of Trade had revoked the electric lighting order granted to the borough, and a committee was appointed to confer with the Urban Electric Supply Company (Edmundson's Electric Corporation, Limited), who have just deposited an application for a provisional order.

Hammersmith.—Extensions of mains in Rylett-crescent and Girdlers-road, to cost £201 have been agreed to. Since the last meeting of the committee 36 additional consumers have been connected, representing a maximum of 888 8-c.p. lamps; these added to the number previously reported, show a total of 746 consumers taking current from the mains.

Nantwich.—The Urban District Council have approved the appointment of Mr. W. H. Trentham, of Victoria-street, Westminster, and Mr. G. R. Peers, of Manchester, as joint engineers in connection with the proposed electric light installation and refuse destructor, the terms of such appointment to be embodied in an agreement to be prepared.

Aberdeen.—At the Town Council meeting recently it was reported that in the central part of the city great improvement had been effected in regard to electric lighting. A report of the Watching, Lighting, and Fires Committee recommended that 18 electric lamps should be erected in Powis-terrace at an estimated cost of £650. The report was adopted.

Hull.—The Electric Light Committee of the Corporation have decided to increase the salary of their electrical engineer (Mr. A. S. Barnard) by £50 per annum. We learn that it is probable that the Tramways Committee will also make a further addition to this amount in respect of his services in connection with the electrical installation of the tramways.

Electric and General Investment Co.—The directors have declared an interim dividend of 10 per cent. on the capital paid up on the ordinary shares of the Company, being 2s. per share, less income tax. The dividend is for the six months ended the 30th ult., and will be payable on Jan. 2, 1901, to those shareholders registered on the books of the Company on Nov. 30, 1900.

Sleaford.—The Local Government Board have followed the granting of an electric lighting provisional order by sanctioning a loan of £7,000 to carry out the project, the money to be repayable in 25 years. There is considerable indignation on the part of the majority of the ratepayers at the action of the Local Government Board, for it is urged by experts that whereas only a two-wire system is to be laid at present, larger works and the three-wire system will have to be substituted should the town continue to increase in size, thereby greatly adding to the outlay and placing an unnecessary burden upon the ratepayers.

Stock Exchange.—The Stock Exchange Committee have appointed Jan. 3 a special day for Kalgoorlie Electric Power and Lighting Corporation's 150,000 6 per cent. cumulative preferred shares of £1 each, 10s. paid, Nos. 1 to 150,000; and Marconi's Wireless Telegraph Company's 77,083 shares of £1 each, fully paid, Nos. 1 to 40,000 and 100,001 to 137,083, and 60,000 vendor's shares of £1 each, fully paid, Nos. 40,001 to 100,000. Applications have been made to the committee to appoint a special settling day in British Motor Traction Company's 205,557 5 per cent. cumulative preference shares of £1 each, fully paid, Nos. 1 to 205,557, and to allow Dick, Kerr, and Co.'s 24,000 5 per cent. cumulative preference shares of £5 each fully paid, to be quoted in the official list.

Appointments Vacant.—A large Continental works, manufacturing generators, motors, and electrical apparatus of every description, require a manager and engineer to take charge of business in the United Kingdom and Colonies. Machinery already well introduced in Great Britain.—The Council for the Foreign Community of Shanghai require a municipal electrical engineer. Salary at present rate of exchange, about £510 per annum, with quarters, coal, gas, and medical attendance. Full particulars of these vacancies appear in our advertisement columns.—The Corporation of Rotherham invite applications for the post of borough electrical engineer. Salary, £200 per annum. Applications must be received at the office of Mr. H. Hampton Copnall, Rotherham, endorsed "Electrical Engineer," before noon on Jan. 14.

Bolton.—On Friday night the last laid portion of the Corporation electric tramways to Deane and the Hulton district was first utilised since its completion, the members of the Tramways Committee, with their general manager (Mr. H. England), and the borough electrical engineer (Mr. A. A. Day), taking a trial trip over the new route, the opening of which for traffic this week will prove a boon to a large residential district. The Brush Electrical Engineering Company are supplying portion of the cars required by the Corporation, and the first of these delivered, which is a vehicle on the bogie principle, with a carrying capacity for 71 passengers, was utilised, and ran very satisfactorily. With a view to further extending the tramways, reconstructing the old lines, and widening the streets of the town, the Corporation has resolved in the next session of Parliament to obtain borrowing powers to the extent of over £500,000.

Digitized by Google

Bath.—The Electric Lighting Committee have recommended an application to the Local Government Board for sanction to borrow £4,000 to cover the cost of purchasing land lying between the Great Western Railway Station and the old bridge.

Long Eaton.—The District Council decided to send the electrical engineer's plans and specifications for an electric lighting scheme for the town to the Board of Trade for approval. It was also resolved to apply to the Local Government Board for sanction to borrow £15,000 for carrying out the scheme.

Bexhill.—At the recent enquiry Mr. Le Feuvre, electrical engineer to the Council, described the electric lighting plant. The Council had not decided what the price should be for lighting, and the minimum cost now was 2·4d. per unit. At the present time extra money was being borrowed to extend the machinery.

Pollak-Virag Telegraph.—When Mr. Pollak first brought out his system of rapid telegraphy great objection was taken to the wavy signals of the siphon recorder. The Austrian papers now mention that under the improved Pollak-Virag system this has been overcome, and that recently a message was printed in Latin characters at a rate of 1,000 words a minute—which we doubt.

Openshaw.—At the Manchester City Council meeting on Wednesday attention was drawn to a memorial from Openshaw and district, signed by a large number of business firms, complaining of insufficient telephonic accommodation, and asking that it should be rendered efficient by the coupling up of certain connections and extensions. The matter was referred to the Telephone Committee.

Middlesex.—The County Council have adopted the recommendations of the Parliamentary Committee that the Hampton, the Heston and Isleworth, the Teddington, Hampton, Hampton Wick, and Ham, and the Teddington Urban District Council electric lighting orders be opposed, unless the promoters are prepared to undertake to insert a clause in it providing that the works shall be underground.

Mine-Lighting.—We learn that the Collingwood Goldfields, Limited, Golden Bay, New Zealand, will in all probability shortly light their extensive workings by electricity. The power will be obtained from the water of a neighbouring lake, an unlimited quantity being available at a head of some 200ft. The transmission line will be about half a mile long. Messrs. Adams and Williams are the consulting engineers, and are reporting to the company on the matter.

Barry.—The negotiations between the District Council and the Thompson-street Syndicate, Limited, for the purchase by the former of the railway siding and land belonging to the syndicate at the rear of Thompson-street, Barry Dock, for the purposes of the contemplated extension of the gasworks and the erection of an electric generating station have fallen through, the Barry Railway Company having made a more favourable offer for the acquisition of the property.

Union Light and Power Co.—The Reorganisation Committee of the Union Light and Power Company have announced that on and after Jan. 1 next the National Provincial Bank of England, Limited, will pay to the depositors of bonds under the scheme of reorganisation £5 in respect of each 1,000dol. first mortgage 5 per cent. gold bond deposited, and £2 in respect of each 1,000dol. consolidated mortgage bond deposited. Certificates of deposit must be left with the bank for examination.

Croydon.—The County Council have adopted the Lighting and Electricity Committee's report as follows: "That the borough electrical engineer be authorised to arrange for the laying of tubes to receive the telephone cables of the General Post Office Department in the trenches he excavates for electric light mains along routes where the department desire to go; that the committee have approved form of free wiring agreement; that a low-tension main be laid in Wellesley-road, which will obviate the necessity of supplying transformers from the high-tension main, which is now done; and that the main now in use should afterwards be used for supplying street-lighting by nine arc lamps."

Brighton.—At the last meeting of the Town Council exception was taken to the Lighting Committee's refusal to light Chesham-road and Rock street, Kemp Town, with arc lamps. It was pointed out that the provision of these arc lamps would mean a capital expense of £2 000. The exception was carried by a large majority. The Lighting Committee have resolved to inform the Tramways Committee that they would undertake the supply of electricity to the wattmeter on the tramway switchboard, including the provision and control of sub-station battery, transformer, and tramway switchboard. Mr. Wright is to report upon the rate of charge to be made, and the surveyor is to report as to the cost of constructing an underground sub-station, 80ft. by 30ft. by 14ft., at the bottom of Ditchling-road.

Electric Lighting in London.—At the meeting of the Court of Common Council, held at the Guildhall last Thursday week, Mr. A. C. Morton asked if the City of London Electric Lighting Company had approached the City Lands Committee, and the other committees of the Corporation having the control of electric lighting, with a view to obtaining consent to an increase of the standard pressure in the mains from 100 volts to 200 volts. Was it estimated that the change of pressure from 100 to 200 volts would result in an estimated increased cost of about 25 per cent. to the users of the electric light in the City? Mr. Pryke, chairman of the City Lands Committee, replied that that committee had been approached by the company, and after consideration and advice had decided not to give the required consent. It was estimated that the change of voltage or pressure from 100 to 200 volts would result in an estimated increase of cost to the extent of 20 to 25 per cent. consequent upon the higher voltage and the inefficiency of the lamps.

Catalogue.—The Pond Machine Tool Company have forwarded us a copy of their catalogue compiled especially for the Paris Exhibition. From this it appears that the firm turn their attention chiefly to the manufacture of engine lathes, planing machines, radial drills, boring and turning mills, and railroad machinery for wheels and axles, and a full and interesting description of each of these is given in a separate chapter. The machine tools manufactured by the firm are of the most modern design, massive and substantial in construction, and every convenience is provided for facilitating work. The company have a name for heavy and powerful tools, and those turned out by them are now in use in many of the leading concerns, both in this country and in Europe. The catalogue itself, which is in book form, is handsomely got up, and the important information it contains is in three languages—English, French, and German. It may be mentioned that the company's exhibit at the Paris Exposition secured the grand prix and two gold medals.

Swansea.—The County Council at its last meeting adopted the recommendations of the Lighting Committee, that the town clerk be instructed to undertake, on behalf of the Corporation, to supply the Trustees with current for lighting the harbour at a price per unit equal to the present actual cost to the Trustees, and that the engineer be authorised to expend a sum not exceeding £55 in extending the mains to supply the Grand Theatre. The Electrical Committee's report, adopted at the last meeting of the Council, contained the following resolution: "The question of supplying electricity for the lighting of the harbour was considered, and your committee recommend that the town clerk be authorised and instructed to undertake, on behalf of the Corporation, to supply the Trustees with current for lighting purposes at a price per unit equal to the present actual cost to the Trustees, and, in the event of disagreement as to what the actual present cost per unit to the Trustees is, that the question be referred to a third person, to be agreed upon between the parties." An amendment providing for the addition of the words, "provided that the resident engineer is satisfied that the price covers the cost of production, taking into account the capital which will be expended in new plant necessary for this purpose," was negatived.

Kingston.—The Town Council have amended their application for an electric lighting loan by adding £2,800 required for an additional exciting dynamo and engine and an extra arc lighting dynamo and engine at the electric lighting works. The total sum, therefore, amounts to £17,800. The Hampton Wick District Council have informed the committee that they have agreed to the terms of a company, as those terms seemed more advantageous than those of the Corporation. The electrical engineer has been asked by the Teddington Urban District Council to submit a report to them in regard to their proposed application to the Board of Trade for a provisional order for powers in regard to the electric lighting of their district. The committee have consented to this, and when their report came up for discussion at the Council meeting last week someone remarked that if the engineer, instead of attending smoking concerts or enjoying his leisure in a hundred other ways, chose to spend his time in preparing the Teddington report, the Corporation would gain rather than lose by the preparation of that report, because it took the engineer away from the daily routine of detail duties, and gave him the opportunity of looking at a lighting scheme as a whole from its inception to its completion.

Derbyshire and Nottinghamshire Electric Power Co.—We have now received particulars of the Bill deposited in the Private Bill Office of the House of Commons to incorporate and confer powers on a company to be known as the Derbyshire and Nottinghamshire Electric Power Company. The Company is to be established for the purpose of producing and supplying electrical energy within the whole of the county of Nottingham and the county of Derby, except that part of Derbyshire which lies to the south of the River Trent and to the north-west of the boundary between the unions of Bakewell and Chapel en-le-Frith. The share and loan capital of the proposed company is fixed at £2,400,000, of which £600 000 may be raised by the issue of debenture stock, and £1,800 000 by the issue of £1 shares, but with the right to divide these shares into preferred half shares and deferred half-shares. The Company ask for powers to proceed to acquire the lands authorised to be taken under this Bill as soon as £100,000 of the capital of the Company shall have been subscribed under contract binding the parties. The promoters named in the Bill are Sir Edward Hamer Carbutt, Bart., Mr. F. Faithfull Begg, Mr. F. Carver, Mr. F. Clench, Mr. Duke Fox, Mr. Archibald Grove, Mr. M. H. Mills, Mr. W. O. Plowright, and Mr. J. W. Thonkerey.

Large Power Scheme.—The Westinghouse Companies' power works at Messena, on the St. Lawrence River, which it is hoped will commence the supply of electricity in about July next year, is to be of larger capacity even than the world famed Niagara plant. Since 1895 there have been installed at Niagara 10 Westinghouse electric generators of 5,000 h.p. capacity each. For the St. Lawrence Power Company 15 Westinghouse generators, of 5,000 h.p, each, are under construction. The power-house is being built on the bed-rock of the Grasse River, and will be about 700ft. long by 150ft. wide. Each of the turbines will consist of a set of six wheels, produce 6 000 h p., and be directly coupled to one generator. The town of Messena is situated between the St. Lawrence and Grasse rivers, which at this point are almost parallel streams, separated by a distance of less than three miles, and with the St. Lawrence about 36ft. higher than the Grasse.

Digitized by Google

The canal conveying the water from the St. Lawrence to the power-house is large enough to accommodate large lake vessels, and in the future a lock will probably be constructed to pass these vessels to and from the canal and the Grasse River. The deepening of the latter would make Messena both a lake port and a seaport. To develop 75,000 h.p. the canal will need to be widened to a width of 263ft., and the Grasse River will have to be deepened. It is expected that a part of the plant will be in operation supplying the surrounding neighbourhood with electric power during the coming summer.

Sunderland.—At a recent meeting of the Chamber of Commerce an interesting discussion took place as to the proposed municipalisation of telephones. Mr. Heaviside, who had charge of this district on behalf of the Post Office and who attended by request, said that the Postmaster-General was offering in Sunderland to establish an exchange circuit in accordance with the new terms recently adopted. The Post Office applied in the middle of February for wayleaves to cover the whole of the town with a service of telephones, but from that time to the present the Government had not got that sanction from the Corporation, and the matter was further complicated owing to the Corporation not having decided whether or not they would apply for a license for the municipalisation of the system. If that license were granted, of course, the Government would enter into competition in Sunderland, but, on the other hand, the Government were not justified in making any great expenditure if a license were to be granted to Sunderland. If the Post Office established a large centre in Sunderland the communication with the trunk calls would be more rapid than through other systems, because two connections would be obviated which would otherwise have to be made. He added that Halifax, Portsmouth, Brighton, and Glasgow had already applied for licenses, but none had yet done anything in the matter further than that. It was a very big question, and a matter in which expert knowledge of a very special kind was wanted. It was very different to working with heavy currents, for the currents were microscopic, and the apparatus extremely delicate, and it required almost infinite knowledge of details to make it successful. The Government were unable to do anything until the Corporation had decided what they would do in the matter.

TRACTION.

Colchester.—The Corporation have sealed their application for a tramways provisional order.

Rawmarsh.—The tramway negotiations are proceeding. No definite answer has been arrived at.

Folkestone.—The Town Council have formally confirmed their resolution to apply for a tramways provisional order.

Cleveland and Durham Electric Power Co.—A conference has been arranged of councils affected by this company's Bill.

Brighton.—The Tramways Committee have approved the plan of the proposed electric tramways subject to certain amendments.

Gloucester.—A deadlock has arisen between the Corporation and the tramways company with regard to the proposed tramways.

Maryport.—The District Council recently appointed representatives to attend a conference of local authorities concerned in the roads over which it is proposed to run electric trams.

Bristol.—Colonel von Donop, R.E., inspected the permanent way and the general equipment of the Bristol electric tramways on Thursday and Friday. There are now 30 miles open.

Huddersfield.—Mr. H. N. Thomas, the resident engineer and clerk of the works at the electrical power station, has been appointed electrical engineer at a salary of £300 per annum.

Grimsby.—On Thursday last week the first trial car was run on the new tramway line diverting the up traffic in Victoria-street round by George-street, Osborne-street, and Bethlehem street.

Falkirk.—The Town Council last week agreed to the draft tramways provisional order which the Roads Committee had approved of subject to certain proposed amendments being given effect to.

British Columbia Electric Railway.—The directors have declared an interim dividend on the ordinary shares at the rate of 4 per cent. per annum, free of income tax, for the six months to Sept. 30 last.

Hull.—The city engineer is now engaged on the preparatory work in connection with the wood paving and the laying down of tramlines in the Market-place and Queen-street. The actual work will probably commence shortly after Christmas.

Elgin.—The County Council have received a petition from the villagers of Hopeman asking the Council not to consent to the provisional order which it is proposed to apply for to authorise the construction of a tramway between Clash Quarry and the village of Hopeman.

Twerton (near Bath).—The Parish Council has expressed its satisfaction of the plan of the proposed route and extension of the electric tramways from Twerton Station to Lower Mills, and the clerk has been instructed to write the company and the Rural District Council on the subject.

Birkenshaw.—At the monthly meeting of the District Council last week, the clerk was empowered to take the necessary steps to purchase, at the expense of the British Electric Traction Company, the portion of the Dewsbury, Batley, and Birstall Tramway within the Birkenshaw township.

Aberdeen.—The Tramways Committee have agreed to recommend the Council not to take the ground at Dee Village for tramway car sheds. The following committee has been appointed to define the duties of the manager of the tramways and the electrical engineer: Lord Provost Fleming, Councillor Wilkie (the convener), Treasurer Bisset, Councillors Johnston, Geo. Brown, Kemp, and Glass. The question of widening Park-street is being considered by a sub committee.

Liverpool.—The proposed line of the Manchester and Liverpool Electric Express Railway is to be laid in a cutting, instead of being on the viaduct principle, as previously proposed. This will be covered over at intervals in a similar way to that in which the London underground was constructed, and it is proposed to leave open spaces over the tunnels so that the Corporation may make gardens, and thus create a beautiful promenade a mile long through the worst slum property of the town. The capital of the company is now fixed at £2,100,000.

Greenwich.—At the last meeting of the Borough Council a letter was received from the South-Eastern Metropolitan Tramways Company, whose lines run from Greenwich to Catford, informing the Council that they had applied to the Board of Trade for their approval to the reconstruction and electrical equipment of the company's tramways upon the Schuckert surface-contact system, and that the Board in their reply stated that they desired to learn the views of the several local and road authorities concerned. The matter was referred to the Highways Committee.

Charing Cross, Euston, and Hampstead Railway Extension Bill.—The committee of the Hampstead Heath Protection Society have passed the following with regard to this Bill: "That this society objects strongly to the proposed extension on the grounds that tunnelling under the heath may injure it, and that the threatened erection of a station on the summit of the Hampstead hill, or on or adjacent to any part of the heath, would be a substantial injury to the heath. The society will therefore use every effort to oppose the proposed extension as shown on the deposited plans."

Middlesex.—The County Council, on the recommendation of the Parliamentary Committee, have agreed to oppose the Kingston Corporation Tramways Bill and the London United Tramways Bill with the view to the protection of county interests. The Parliamentary Committee's recommendation that the County of Middlesex Light Railways (Joint Order) be granted to the County Council alone, and, further that a supplemental agreement be come to with the Metropolitan Omnibus and Tramways Company accordingly, was adopted last week. The County Council have appointed a Light Railways and Tramways Committee to take charge of the construction, control, and management of light railways and tramways which may belong to the County Council.

Scarborough.—The Streets and Buildings Committee have recommended the Corporation to withhold for the present their sanction to the proposed scheme of the electric tramways company. Two clauses in the proposed Bill are strongly objected to. One is in reference to the period of purchase and the other the levying of toll for transit over the Marine Drive. The company proposes 50 years as the period of purchase, but the committee favour 21 years. The company also proposes to pay half tolls for trams running over the drive, and in return to illuminate the drive by electricity. The committee contend that this would not be fair to the owners of other vehicles who use the roadway. The committee's recommendation will, it is anticipated, be unanimously agreed to at the full Council meeting.

Oldham.—The Middleton-road section of the new electric tramways was opened on Saturday. The centre under-running overhead trolley system has been adopted. The steel standards are of the side bracket type, with cast-iron ornamental bases and ornamental wrought iron scrollwork and collars designed by the borough engineer. The electrical energy is being supplied by the Electricity Committee of the Corporation from their present power station. A new generating station is under construction, and will, when completed, be capable of supplying about 20 000 h.p. In addition to the section just opened, seven miles of track is already completed, and the electrical equipment is being pushed rapidly forward. The total estimated cost of the whole system, with 25 miles of track, excluding the new power station, but including permanent way, electrical equipment, cars, and car depôts, £400,000.

Proposed Metropolitan Railways.—The particulars of the powers sought under the 13 Bills deposited for promotion in the next session of Parliament show a total capital outlay of £24,020,000, made up as follows: City and South London Company, £300,000; Charing Cross, Hampstead, and Highgate, first Bill £1,800,000, second Bill £1,800,000; Central London, £600 000; Brompton and Piccadilly Circus, £1,800,000; Piccadilly and City Railway Company, £1,500,000; line from New King's-road to Buckingham Palace-road, £1,250,000; line commencing in Islington and terminating at a point under Drummond-street, St. Pancras, £420,000; line from near Charing Cross to Park lane, Kensington, and Hammersmith, £2,250 000; from Victoria to City, £2,100,000; from City to Peckham, £3,300,000; line from City to Tottenham, Walthamstow, and Leyton, £4,500,000; and from City to Waltham Abbey, £2,400,000.

Tube Railways and Householders.—A meeting of the Court of Common Council was held at Guildhall on Thursday week, the Lord Mayor presiding. Sir Prior Goldney, the Remembrancer, replying to a question by Mr. Deputy Johnson, said he was aware that a great deal of public attention was being directed to the construction and working of what were called "tube railways" in London. Some half dozen Bills had been deposited in Parliament

Digitized by Google

in connection with new railways of the kind, but until the middle of January, or, perhaps, until the commencement of the session, it would not be known which of them would be proceeded with. Householders who were apprehensive that their buildings would be damaged by the vibration caused by the running of the trains ought to ascertain all necessary data in anticipation of the Bill being prosecuted. There might be questions whether the powers of the railway companies had been exceeded or not in the manner in which the lines had been constructed. The Board of Trade had taken exceptional steps to estimate the facts for themselves by appointing a committee of experts to ascertain the causes and the extent of the damage, and persons seriously injured should lay their evidence before the Board, and no doubt it would be satisfactorily dealt with. It was anticipated that the committee would report in time to get a stock clause inserted in all future Bills for the protection of the public.

Wolverhampton.—We notice that "Perplexed" writes to the *Financial Times*, giving his experience of the "so-called voluntary winding-up" of the Wolverhampton Tramways Company. He states that "In the month of April last the Wolverhampton Company sold its tramway, with its cars and stock, to the Corporation of that town, but only in so far as the tramway was included in the town boundary. The Corporation paid the tramway company the sum of £22,500, but to this day no record of the transaction have the shareholders received, neither has a fraction been paid to them. Enquiries have elicited the remarkable reason, given by the secretary of the tramway company—viz., that a separate sale of the tramway property outside the town of Wolverhampton to the British Electric Traction Company has not been completed in consequence of a dispute having arisen months ago as to the terms on which this outside property should be taken over, and arbitration was agreed upon. If this arbitration has commenced it is high time it was completed, but as to why the large sum of money already long since paid by the Corporation to the tramway company has not been distributed to shareholders I can obtain no explanation" "Perplexed" goes on to express the opinion that had the High Court officials had this business placed in their hands shareholders would months ago have received a large proportion of their money, and probably would have settled the alleged dispute that had arisen. The writer, in conclusion, contends that shareholders should have been called together and the delay explained why money had been so long locked up by the directors of the tramway company, and why they had not been furnished with a detailed account showing the actual position of affairs.

Kingston-on-Thames.—We understand that the Corporation and the London United Tramways Company are still disputing over the question of the ownership of the lines to be run through the borough. The Corporation are endeavouring to obtain a provisional order to become the tramway authority for the borough, and are warmly opposing the company's Bill. A committee of burgesses has been formed to support the Corporation in their effort to obtain this provisional order, and it would seem from certain correspondence which has been forwarded to us that there is a good deal of excitement in the locality over the question. It is stated that by the terms offered by the company, Kingston would get ½ per cent. on the estimated outlay of the line, nothing definite for track maintenance, and the power of purchase at market value at the end of 25 years. These terms do not please the Council, who say they do not accord with the interests of the borough, and cannot be accepted. The Council will, therefore, persevere in their opposition to the company's Bill and with the promotion of their own. The Tramways Special Committee's report states that the actual proposals are more prohibitive of eventual purchase than ever. The company seek to abrogate Section 43 of the Tramways Act, 1870, and, in addition, require that the right of purchase shall be deferred from 21 to 25 years, and shall only then be exercised on payment of a "going concern" price. The committee, however, say that before any local authority in the Surrey portion of the company's scheme can exercise the power of purchase, each of such authorities must agree to purchase the portion of the undertaking situate in the district of such authority. Barnes District Council is one of these authorities, and the proposed line in that district is unconnected with the others; so that, if it should not at one and the same time suit the purposes of Barnes to purchase, none of the other authorities could do so. Any proposal more preposterous, the report goes on to state, it would be difficult to imagine. The company's conditions, contrary to the interests of the borough as they previously were, are now, as contained in their Bill, still worse.

NEW COMPANIES.

The following new companies have been registered:

British and Foreign Electrical Vehicle Company, Limited.—Capital of £150,000 in £1 shares. Object: to acquire the assets of the Leecoll Electric Battery Company, Limited, together with one-half share in the Leecoll patents in various countries. The notice of the present issue of capital appeared in our last issue.

Elden Engineering Company, Limited.—Capital of £2,000. Object: to adopt an agreement with R. Hancock, and to carry on the business of consulting, mechanical, and electrical engineers, etc.

Electrical Navigation Protection Company, Limited.—Object: to carry on the business of electrical engineers, constructors of cables, wires, lines, and works, generators and distributors of electricity, electric light contractors, electricians, etc.

L. Gardner and Sons, Limited.—Capital of £50,000 in £1 shares. Object: to acquire the business carried on at Barton Hall Engine Works, Patricroft, Lancashire, as L. Gardner and Sons, and to carry on the business of mechanical, electrical, and general engineers, etc.

Hillgrove and Armidale Electrical Corporation, Limited.—Capital of £70,000 in £1 shares. Objects: to adopt an agreement with the International Railway Corporation, Limited, for the sale of the undertaking described as the Hillgrove and Armidale Water Power Electric Company, and an assignment between the said two parties and Crompton and Co., Limited, of an agreement providing for the local management thereof, to acquire the benefit of certain powers granted by the Legislature of New South Wales, to carry on in the county of Sandon and elsewhere in Australia the business of an electric light and power company, to facilitate the navigation of the River Gyra, and to carry on the business of electricians, mechanical and electrical engineers, to construct and maintain rail, tram, and omnibus systems, to lay down cables, wires, lines, accumulators, dynamos, etc.

Kapunda Copper Mine, Limited.—Capital of £120,000 in £1 shares. Object: to acquire a mine and other property at or near Kapunda, South Australia, and to carry on the business of miners, explorers, smelters, and refiners of ores, metals, and mineral substances, engineers, etc.

W. T. Kent and Co., Limited.—Capital of £250 in £1 shares. Object: to acquire W. T. Kent's patents for improved cup and ball joints for gas pendants and the like, and apparatus and machinery for the same; and to carry on the business of gas and electric light fittings, etc.

W. S. Laycock, Limited.—Capital of £150,000 in £1 shares. Object: to carry on the business of railway plant and stores contractors, automatic, pneumatic, electric, and other coupler and brake manufacturers, etc.

Locomobile Company of Great Britain, Limited.—Capital of £100 in £1 shares. Object: to manufacture and deal in vehicles, whether worked by animal traction or by steam, oil, electricity, or other mechanical power, etc.

Murtega Minerals Company, Limited.—Capital of £80,000 in £1 shares. Object: to acquire and work mining properties in Portugal or elsewhere, to explore mines and land supposed to contain minerals, metals, etc., to construct and maintain rail and tram roads, wharves, docks, piers, warehouses, and other buildings, telegraph and telephone systems, as producers and suppliers of gas and electricity for the purposes of light, heat, or power.

Northern Counties Traction Company, Limited.—Capital of £5,000. Object: to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for all purposes, etc.

Rollason and Eccleston, Limited.—Capital of £1,000. Object: to acquire the business of Rollason and Eccleston at Birmingham, and to carry on the business of electrical and general engineers, etc.

Sarragoza Zinc Mines, Limited.—Capital of £60,000 in £1 shares. Object: to adopt and carry into effect an agreement made by this company with the Rio Tenido Copper Mines, Limited, for the acquisition of certain mines, mining property, etc.

A. Sauvee and Co., Limited.—Capital of £50,000 in £1 shares. Object: to acquire the business carried on by A. Sauvée and Co., at Union Works, 60, Park street, Southwark, and to carry on the business of engineers, machinery manufacturers, metal workers, metallurgists, electrical engineers, hardwaremen, manufacturers of rolling stock, etc.

Slough Creek, Limited.—Capital of £200,000 in £1 shares. Object: to acquire the business of the Incorporated Exploration Company of British Columbia, Limited, to adopt an agreement with the said company and its liquidator, and to carry on the business of miners, engineers, etc., to construct and maintain rail and tram roads, wharves, docks, piers, warehouses, and other buildings, telegraph and telephone systems.

Sneyd Collieries, Limited.—Capital of £250,000 in £10 shares (10 000 6 per cent. cumulative preference). Object: to acquire the business of the Sneyd Colliery and Brickworks, Limited (incorporated in 1881), to adopt an agreement with the said old company, to carry on the general business of miners, and to construct and maintain telegraph and telephone systems.

Whimwell Copper Mines, Limited.—Capital of £150,000 in £1 shares. Object: to adopt and carry into effect an agreement made by this company with the Bank of New Zealand for the acquisition of certain mines, mining rights, etc.

Wright's, Limited.—Capital of £2,000. Object: to acquire the business of W. Wright and J. Holdsworth at Ashton-under-Lyne, and to carry on the business of mechanical and electrical engineers, electricians, etc.

PROVISIONAL PATENTS, 1900.

DECEMBER 14.

22789. Improvements in the electrolytic production of tubes, sheets, and wires. Sherard Cowper-Coles, 82, Victoria-street, Westminster, London.

22801. Improvements connected with electric lamps. Walter McGregor-Douglas, 15, Water-street, Liverpool.

22848. Improvements in arc lamps. Joseph Devonport Finney Andrews, 75, Fulham-park-gardens, London.

22819. Improvements in high-tension electric fuses. August Eckstein and Albert Julius David Krause, Peel Works, Adelphi, Salford, Manchester.

22824. System of distribution for independent polycyclic electric currents. Engelbert Arnold, Ole Sivert Bragstad, and Jens Lassen la Cour, 47, Lincoln's inn-fields, London.

22851. The automatic electric post. Edward Léon Gordon, 65, Chancery-lane, London.

22872. A process for increasing the luminosity of electric incandescent lamps. Erasmus Bushe, 32, Bullingham-mansions, Kensington, London.

22902. Improvements in electrolytic methods and apparatus. Edwin Edser and Meyer Wilderman, 18, Southampton-buildings, Chancery-lane, London.

DECEMBER 15.

22910. An improved means for tilting the shades and lamps of electric lighting pendants. Joseph Boulton Belcher, 35, Lichfield-road, Stafford.

22926. The Facile electric shade remover. Alexander Morrison, Hazlewood, Barlow Moor-road, Chorlton-cum-Hardy, Manchester.

22933. Improvements in combined electrical transformers and choking coils. August Eckstein and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

22956. Improvements in coherers. Leslie Bradley Miller, 93, Hatton garden, London.

22958. Improvements in or relating to safety devices applicable to trolley poles and like current collectors for electric railways and tramways. Phelan McCullough, Thomas Blaney, and Robert Baron, 6, Lord-street, Liverpool.

22972. Improvements in and connected with the electric lighting of railway and other vehicles. Edwin Mumford Preston, of the firm of J. Stone and Co., 77, Chancery-lane, London.

22982. Improvements in holders for globes, reflectors, and the like for electric incandescent lamps. George Chisholm, 5, Corporation street, Birmingham.

22987. Improvements in wireless electric signalling apparatus. Charles George Fernie, 22, Glasshouse-street, Regent-street, London.

COMPLETE SPECIFICATIONS ACCEPTED

To be published on Jan. 5.

1900.

2897. Electric railways on a surface-contact system. Chapman.

9511. Construction of swivel heads of electric car trolleys. Cuttler.

17467. Telephone switchboards. Cedergren and Kähr.

19500. Electric switches. British Thomson-Houston Company, Limited. (Hewlett.)
